Sectional Water-Jacket Furnaces.

When carbonates of lead or copper or metallic copper ores contain a sufficient percentage of those metals to smelt without the addition of any other flux, their treatment in the water-jacket smelting furnace is the simplest possible form of smelting, sometimes requiring nothing but fuel and ore. Frequently the percentage of metals is too low to smelt, or the ores may contain copper pyrites and glance and galena. In preparing the last-named ores for the furnace, miners are met with the complex side of the smelting process; mixtures of iron ore, limestone or silica are found necessary, and to determine when they are required, and how much of each must be added to the ores, is the problem that must be solved to work these ores successfully. It often happens that ores of a different character are at hand, which flux each other to a great extent, in which case they are mixed together as required and then the necessary flux added.

The cut on this page shows a galena silver-smelting furnace, with water-jacket rectangular in form, built in sections and capable of being extended, so as to give a daily capacity of sixty tons of ordinary smelting ore. These smelters have been quite generally adopted by the best reduction works in the East, and are found to give excellent results. The regular sizes are 36 by 42 inches, and from that up to 36 by 78 inches, though special sizes are also built to order by the Risdon Iron Works of this city.

A REDUCTION in the wages of miners is announced to take place in some of the large mines of Utah. The mine-owners of Bingham say that on account of the low price of silver not only must the miners' wages be reduced, but railroad and smelting rates must be lowered; otherwise, they will be compelled to close down. The owners of mines in Tintic tell the same story, and unless something is done to appreciate the price of silver, a general reduction of wages or shut-down of the mines will take place in Colorado, Idaho, Utah and Nevada.

THE North Star Mining Company, of Grass Valley, has recently declared and paid a \$50,000 dividend. This makes the eighth dividend declared by the present company, making an aggregate of \$400,000. The seventh dividend was declared a year ago. The North Star is reported to be looking very well at the present time, making the prospects good for future dividends.

THE Champion Mining Company, Nevada Co., has made arrangements for the erection of new hoisting works soon, to be put up in place of the present works, which are to be placed on the old Merrifield mine, that property being owned by the Champion Company. The change of machinery, etc., will not seriously interfere with operations in the mine.

THERE is a gold excitement in the Wichita mountains, about 75 miles southwest of El Reno, Oklahoma. The new El Dorado lies within the forbidden territory belonging to the Kiowa and Comanche Indian reservation.

COLORADO, in looking out for something to mine in addition to silver, thinks its mines of asbestos are richer than those of Wyoming, and wants some one to start in and work its deposits.

ACADEMY OF SCIENCES.—At the annual meeting of the California Academy of Sciences, held Tuesday evening, the following officers were elected to serve during the present year: President, H. W. Harkness; first vice-president, H. H. Bahr; second vice-president, J. G. Cooper; corresponding secretary, T. S. Brandegee; recording secretary, J. R. Scupham; treasurer, L. H. Foote; librarian,

The State Power House.

The State Power House lately completed at the Folsom Prison is a massive structure of solid granite masonry. It is 170 feet long, 72 feet wide, and 28 feet high in the clear. It is situated about 206 yards below the dam of the Folsom Water Power Company. It is here the State will receive return for the labor furnished in building the great dam and canal. This latter was built for the Folsom Water Power Company by convict labor, and the State is entitled to an aggregate of 800 horsepower. This will be utilized for electric lighting, about the shops, and in the factories and mills likely to be established later by the State.

The power is caught up by six 87-inch Leffel Turbine wheels, which, running at full capacity, give each 134 horsepower. From the bed of the canal to the bed of the tailrace the fall is eight feet. At present there will be one duplex compressor of 180 horsepower, and one 3-throw irrigation pump with a capacity of 1000 gallons a minute. This latter will furnish water to a large reservoir on the high ground for general ranch, orchard and garden purposes. The power furnished by the compressor will be used by the engines and Ingersoll drilling machines for quarry work, and steam will be entirely dispensed with. All the great watergates about the dam and power house, aggregating 20 in number, will be lifted by hydraulic force. This is generated by a 3-throw hydraulic pump which forces the water from the canal, under the accumulator. This latter is a huge iron box 5 feet in width and 10 feet in length and height; within it is a 12-inch piston carrying a weight of 60 tons, which is lifted to a height of 10 feet by water from the hydraulic pump. This, together with the irrigation pump, was furnished by the Risdon Iron Works of this city. The great compressor was built by the Union Iron Works. The turbines are placed longitudinally in the power house and geared to a single shaft from which the power is transmitted to the compressor, by rope belting.

The water to the turbines enters through six double arches the width of the canal being equal to the length of the power house. To guard against the accumulation of slickens in the canal a hydraulic jet is so placed as to sweep across the canal and flush it free of the slickens that would otherwise gather before the turbine gates. Escape gates are conveniently arranged along the canal, which will also aid in flushing.

It is expected to have the machinery in place and everything in readiness for producing power by the middle of January. The work has been done under the general management of Mr. Chas. Aull, the warden. The actual work of construction of the power house and the placing of machinery has been under the superintendence of Mr. Chas. Matheson, who some years ago supervised the sinking of the combination shaft at Virginia City, by which work he is known to

many mining men. The State has one more section of canal to build below the power house, and its work in this regard will then be done. The Water Power Company will complete the canal to Folsom, at which point it will have its own plant, from whence it will derive power for the intended sawmills and transmit the surplus to Sacramento.

MINING companies having offices in this city paid \$135,250 in dividends in December.

CAST IRON SECTIONAL WATER-JACKET SMELTING FURNACE.

Carlos Troyer; director of museum, J. Z. Davis. The board of trustees consists of W. O. Burnett, Charles F. Crocker, D. E. Hayes, E. J. Molera, George C. Perkins, Adolph Sutro, John Taylor.

THE Rich Bar Placer Gold and Mining Company has been organized in Oakland, with O. F. Sites, F. B. Whiting, S. W. Bugbee, A. M. Benham and R. B. Snell as directors. The capital stock is \$500,000.

Comment.

Governor Markham is decidedly of the opinion that it is the duty of Congress to revive hydraulic mining in California. In his message to the legislature on Tuesday occurs the following paragraph: "In my inaugural address I said all that I deemed necessary upon the mining question in this State, and I say again that I meant every word that I said. I can only reiterate that we must look to Congress for assistance, both for our mines and streams. This request should be made upon the hypothesis that it is the duty of the Government to provide means whereby the important industry of mining can be revived without inflicting substantial injury to other interests. I honestly and firmly believe this can, and some day, will be accomplished."

The miners of this State owe a debt of gratitude to this gentleman, who is the first Governor of California for years who has been plain and outspoken on this subject. It must be remembered, too, that he comes from a section of the State where there are no hydraulic mines. It is but just to say that the recommendations made by the Governor in his inaugural address ultimately led to the action of the legislature which brought about the miners' movement last year and the subsequent legislation in Congress. What he says in his message this year still further strengthens the hands of the miners and will have great influence with the legislature in any measures which may come before it.

It does not seem to be yet fully decided as to the place of construction of the new naval vessels. Dispatches from Washington state that one of the vessels will be built in this city, while late advices are to the effect that Mr. Scott, who is in Washington, thinks both contracts will go to the Cramps. A definite decision will doubtless be reached in a few days. It is to be hoped that the Navy Department can see some way by which it can have one vessel built here. The Union Iron Works people have spent large sums to equip their yard, and they ought to be given business enough to keep it going. They have facilities for everything now except the armor-plates, which have to be shipped from Pennsylvania, and can build a vessel as rapidly as at any eastern yard. In case neither of these contracts come to this coast, many skilled workmen will have to be discharged from our local shipyard. There is small encouragement for them to remain here unless they have steady work, and as the Government may at any time need these vessels, it ought to make suit-

able provision for dividing its work in such a way that both sides of the continent may get a share.

Rather a curious cause for delaying railroad trains was that met at Port Costa this week. The big ferry boat which carries the trains across Carquinez Straits to Benicia was unable to get all the way into the slip on the Port Costa side because it got filled up with floating tules coming from the overflowed lands up the river. The current brought the tules in great quantities into the slip, and when the big boat came in she pushed them in front of her, wedging them under the apron as would a huge hay press. They were then unable to lower the apron so as to take the cars aboard. This happened twice in one day, and at one time caused a delay of four hours with the trains. A gang of men had to go under the wharf and cut the tules out in bunches before a landing could be made.

It is reported that about 7000 men have gone to the San Juan placers in southern Utah, and they are coming in at the rate of 600 a day. They are scattered over a territory 150 miles in extent. Gold is found all over that region. The diggings begin near Bluff City and extend 250 miles along the San Juan and the Colorado river and over the adjacent country. Reports indicate, however, that thus far only a few rich spots have been found, and that much of the ground, while it contains gold, will hardly pay to work. At this season it is a very cold region, and there will doubtless be much suffering among those improperly equipped. A placer excitement, no matter where it is, will attract miners and prospectors as nothing else will. They all remember the early days of California and Montana, and will undergo all sorts of hardship to get on the ground early in hopes of making a stake quickly. The country down there is not a good one for poor men, and many are doomed to disappointment.

Undeveloped Mining Claims.

In a recent issue of the MINING AND SCIENTIFIC PRESS we took occasion to urge upon owners of claims to abandon the idea that at no distant day the long expected purchaser would be found to invest his money in a property upon which only assessment work had been done, showing mere suspect holes. The day has passed when the tenderfoot and inexperienced customer, in his anxiety to own a mine, could be persuaded to buy an undeveloped claim. They have grown wiser by experience. The probabilities are that the owners of such have wasted the time that if devoted to the object of development would have resulted in determining the value of their claims and very likely have opened up a valuable property; if it proved otherwise, the sooner that fact was known the better.

When the owner of a claim shows no disposition to work it, there is a suggestion of lack of faith on his own part, and this is calculated to impress a would-be purchaser with a suspicion of its merits.

To any person traveling through the mining districts the fact is lamentably evident that the old-time miner is degenerating into a nonproducer; has lost his energies and wastes his time sitting around doing nothing, waiting for something to turn up, while he neglects his claim on the hillside, and while he knows that he could make a couple of dollars or more a day by washing the gravel of a nearby creek. But he will not come to "Chinaman's wages," as he contemptuously calls it.

The energetic spirit of the early day seems to have faded out, with the reduction of earnings and rich placers; but the recollection of those days when miners made their one or two ounces a day is still vivid in the memories of "old timers," and they find it hard to come down to current wages, forgetting the decreased cost of living. So, many of them, because they can no longer earn their \$15 to \$20 a day, compromise by earning nothing. It is true much of the placer ground has been pretty well worked over, and the pay is greatly lessened, but each year after the wash from heavy rains more or less gold is washed down from the banks. This is left to Chinamen to work, and many a dollar is earned by these patient laborers in claims where white men might work if so minded.

It is an exceptional country where any man can earn by his own labor his \$2 or \$3 a day in mining when other resources fail, and he has no quartz claim to work with a prospect of seeing it some day develop into a valuable mine. He should bear in mind that all mines now returning remunerative profits to their owners were once mere prospects, and would have so remained had not the owners developed them to a point to prove their value. There are probably as many good mines or what would prove so by labor awaiting development as have yet been found.

It is one of the peculiar characteristics of the miner that he would rather work for some other man at \$2 or \$3 a

day than work for himself with a prospect of much higher earnings. The complaint of dull times in mining is to some extent the result of the relaxations of effort on the part of the miner. He has grown indolent and indifferent, and contents himself with earning a few dollars to win his daily "grub," and wastes his time that he should employ in working his claim in sitting in the shade and telling stories of the money he made in '49 and '50 and waiting for some greenhorn to come along and buy his undeveloped claim, and this man never comes. There is always a good demand for such properties as promise remuneration for the capital invested, and the complaint that mines do not sell is simply the result of the scarcity of good ones.

There is probably as much gold in California yet untouched as has been produced, and it only requires labor and energy to find it. The question is, are we to leave it to future generations to do so or reap the benefits of its production in this? Agriculture seems to have taken the place of energetic mining to a great degree, and affords occupation for large a population, but there is still a large percentage of idle men who are better skilled in mining, who lack the energy to follow it, and reap the more direct reward of their labor. There are undiscovered millions awaiting the pick to produce it. It is labor alone that will release it from the earth and rock and put it afloat.

THE MINING AND SCIENTIFIC PRESS is able to quote a recent instance brought to its attention as an illustration of the result to a miner, who, after reading our former articles on this subject, went vigorously to work on his claim which he had suffered to lie idle for years, with the result of striking a fine ledge of high grade ore inside of a month, that promises to turn out a big mine, and insure him a competency for life. How many similar instances might we not be able to chronicle if others would follow such an example, and go to work on their long-neglected claims and develop them.

There is plenty of gold yet to be found in California by working for it. It is not the belief in the scarcity of good mines that we complain of, but the want of energy and enterprise lacking to bring the hidden thousands to light. There is no other reason why the gold product of California cannot be doubled. What we need is more of the spirit, energy and industry of the early days. We are taking life too easy and losing our ambition, the result in a measure doubtless of the low cost of living. But should we be content to barely eke out an existence and let the golden prize slip from our hands to enrich future generations for which we are showing so much consideration?

The Governor and the Mining Bureau.

The Governor of California, while he is generally favorable to the mining industry, as shown by his official addresses and messages, does not appear to be entirely satisfied with the State Mining Bureau, or the methods under which it is conducted. In his message to the legislature he recommends some radical changes, in the following language:

The Statutes of 1885, Chapter 166, provide in one sentence that the Trustees "shall have the right to appoint a custodian of the museum and other employees." The very next sentence says the State Mineralogist "shall have the right to appoint a custodian of the museum and other employees, subject to the approval of the Board of Trustees." There is another provision that the State Mineralogist shall consult "the board in all matters of importance"; but it does not in any way place the Mineralogist under any obligation to act on their advice. By a careful study of the statutes cited, it will be seen that the Board of Trustees have really no control of the State Mineralogist or his assistants, except to disapprove salaries or expense accounts. There have been for years many disagreements between the Trustees and the State Mineralogist, growing out of the conflict in the laws referred to and the limited powers conferred upon the board. I think that your honorable bodies should remedy this at your present session. I recommend (1) that the State Mineralogist be placed directly under the control and supervision of the board in all things; (2) that they have the power to appoint and discharge all subordinate officers; (3) that they be clothed with the power necessary to conduct the affairs of their institution; and that they be put on the same footing as other boards and commissions in this State in this respect.

This would, in effect, deprive the State Mineralogist of all the patronage of the Bureau and make him subordinate to the trustees in almost every respect. This would be all very well provided the Governor would exercise judgment in the selection of the board, and pick out men with some knowledge of how an institution of this kind could be made practically useful. The gentlemen selected have usually been those who have made some money in mining or have been identified with the industry in some way. Speaking generally, they have exercised little or no influence with the reports, or with the conduct of the Bureau. This may be due, however, to the conditions stated by the Governor.

If they had been able to exercise any control over the State Mineralogist, they might, to advantage, have studied up the methods adopted and carried out in similar institutions in other countries. At least they could have given more attention to the character of the work carried on,

and endeavored to learn the wants of the mining community. All these matters have been left to the individual judgment of the State Mineralogist. In one instance this official bent almost his entire energies toward perfecting the mineral cabinet, and published extensive catalogues referring to such cabinets. Another one occupying the office shaped his reports with apparent reference to ultimate influence to be gained for appropriations in the legislature. To accomplish this, much "padding" was necessary, and all sorts of mining properties, described at length, in the various counties of the State. To such a length has this latter practice been carried, that this time, the Board of Examiners, (of which the Governor is a member) declined to publish the complete report, printing only the brief report of the trustees, and the introduction by the State Mineralogist. This report also called forth from the Governor the following expression, printed in his message to the legislature:

I have carefully read the biennial reports of the various State officers and public institutions, with the exception of those of the State Mineralogist as originally prepared, the State Agricultural Society, the Railroad Commissioners, the Bureau of Labor Statistics, the State Board of Horticulture, and possibly one or two others, which are so voluminous that none but the unemployed and those directly interested and expecting to derive personal benefit from them can have time to read. While it is the duty of those who prepare these reports to inform the public fully in regard to the conduct of their institutions, very often too little time is devoted by their authors to condensing their statements. Intelligent people do not require arguments, but simply facts, from which they draw their own conclusions. The enormous cost of printing some of these volumes seems to have escaped attention in many cases; notably to that of the State Mineralogist, the cost of printing which, as presented, would have been over \$10,000. I have no doubt that this is a valuable contribution, but I believe that \$2000 worth of intelligent editorial work bestowed upon the manuscript would have saved four times that amount in the cost of printing, and the volume would have been of greater value to those interested. People will not read long, tedious reports, and if it were not for the condensed statements given out through the press the people of the State generally would have very little information in regard to our public institutions.

This criticism is severe, but just, judging from previous reports published. A large amount of what has appeared is of interest only to the owner of the particular mine referred to. We took occasion to make this same criticism on the appearance of the last report, regretting that a more practically useful volume could not have been produced for the money expended. Judicious editing by people familiar with the subject would have been beneficial, as the Governor aptly suggests. There is a tendency on the part of the writers of the articles to make as good a showing as possible, and in so doing the matter has become greatly extended. Very little, if any, of the writing is done by the Mineralogist himself; the report being made up by employees of the Bureau, or by outside contributors.

No attempt has ever been made to gather the mineral statistics of the State from year to year, and for these we must depend upon the Government reports published by the U. S. Geological Survey and U. S. Mint. The technology of the industry has also been neglected, very few articles descriptive of metallurgical methods having been proposed.

It is very evident from the Governor's remarks that he is dissatisfied with the Bureau; and it is also evident that when the legislative committee takes up the report which has been referred to it, the whole conduct of this important State institution will be inquired into. The friends of the Bureau and the miners of the State will have no objection to having it put on a firmer and more practical basis than it is at present, though they will decidedly object to its abolition or curtailment of its scope.

Montgomery District.

We had a conversation this week with Mr. W. P. Miller Jr., assistant superintendent of the Breyfogle Co. in Montgomery district, Nev., a camp in Nye county about 165 miles from the railroad. There is only one company working in the camp now and this is known as the Breyfogle, though it will be incorporated under some other name. This company owns about a dozen claims and is now working six of them. On two, quite extensive work is being done. The deepest shaft is about 140 feet. The ledge is a peculiar one and varies greatly in size. The ore is all free gold. A 10-stamp mill has been built here to be shipped to these mines. To reach this district they go by the Atchison, Topeka and Santa Fe Railroad to Fenner, in San Bernardino county, and go over by team, there being no stage line. There are very few prospectors in the camp now, most of them having dropped out. All the men there are working for wages. There is not even drinking water in the camp, this having to be brought on mules. The camp is on one side of the valley and the water on the other. The new mill will be ready to run in the spring, though the millsite has not yet been chosen.

Mr. Miller says that the Keystone mine, in Keystone district, about 60 miles from Montgomery, is getting out some very rich free-gold ore. They have lately been shipping rock valued at from \$500 to \$700 per ton.

Mining Briefs.

THE Lady Washington, Soulsby, Richards and Grizzly mines at Summersville, Tuolumne county, have been consolidated and bonded by a San Francisco corporation.

BELMONT Courier. The southern parts of Nye and Lincoln counties, Nev., continue to attract restless treasure-seekers. New strikes are being made and that country presents more attractions for industrious prospectors to-day than any other part of the State.

THE gold mines north of Winslow on the lower San Juan are being boomed for a good deal more than they are worth. Little is said of the large chunks of ice and snow that can be panned out there at this season of the year.—Mojave Miner.

TALK about handling ore quickly! Mr. Samuel G. McClure, in an article on the types of vessels built on the great lakes, states that as many as 2000 tons of ore have been dumped into a boat in 45 minutes. It takes a strong vessel to stand such a shock as that.

THE mining industry of Fresno county has been rather dull during the past year, owing to the lack of capital seeking investments in mining properties. There have been many failures in this business in Fresno, but it is claimed this has been due more to mismanagement than to the character of the mines themselves.

COL. Mike Gray headed an expedition in 1872 to hunt for the San Juan gold diggings. He left Pueblo with a party well equipped for the journey. They traveled to within 60 miles of the placers when they were obliged to turn back, owing to the scarcity of provisions and the hostility of Indians.

A STORY of the alleged sale of the great tract of niter-bearing soil near Lovelock, Nevada, has been going the rounds of the press. While it is true that negotiations were pending for such a sale to foreign capitalists, they have just been declared off. It was found that the percentage was too low.

THE Anaconda and St. Lawrence mines at Butte are now closed down so far as the extraction of ore therefrom is concerned. With the closing of these properties the suspension of the ore production by the Anaconda Company is complete. The lower smelter at Anaconda is still in operation, and it is supposed will continue so long as the ore now on hand holds out. Just when the company will resume the extraction of ore from its mines is not known.

Personal.

J. B. LOW, the mining expert, has returned from the East.

W. E. SHARON, superintendent of Yellow Jacket, went back to the Comstock from the city on Wednesday.

JAMES R. RYAN, superintendent of the Hale & Norcross and Andes mines, spent the holidays in this city, but has returned to the Comstock.

MR. CLARK, of the Gladstone mine, Shasta county, has gone up there to see what the new body of ore looks like. It is at such a depth as to be very encouraging.

CAPTAIN H. G. MORSE, of the Oceanic Steamship Co's steamer Alameda, delivered a lecture on Tuesday before the Geographical Society of the Pacific on "Revolving Storms."

It is reported that Alvinza Hayward, the well-known mining millionaire, has taken an interest in the old Hardenburgh mine, and consequently a thorough prospecting will be done.

COLONEL D. H. JACKSON has resigned his position as superintendent of the Holmes mine at Candelaria. He will soon leave for Mexico, where he will take charge of some mining property.

F. L. MORGAN, superintendent of the Needles Reduction Co., is in this city purchasing some machinery to add to the capacity of the mill. He will also purchase a hoist to put in a mine belonging to the company.

W. G. HODSON, secretary of the Shasta County Miners' Association, came down from Redding on Wednesday. He has recently been over into Trinity county, collecting some ores and minerals for the World's Fair Exhibit.

IRA SMITH, the new superintendent of the California Navigation and Improvement Company, who was lately appointed to succeed the late Captain Martin Corcoran, has entered upon the discharge of the duties of his office.

PROFESSOR E. E. BARNARD, Astronomer of the Lick Observatory, has received word from the Perpetual Secretary of the Academie des Sciences of Paris that, at the regular meeting held on the 19th of December, he had been awarded the famous Lalande prize of the Academy. The Lalande prize is awarded annually to the astronomer who shall publish the most useful memoir or make the most important observation. It was undoubtedly given to Professor Barnard in recognition of his discovery of Jupiter's fifth satellite, as announced to the scientific world from the Lick Observatory during last September. This award is considered the greatest honor which can be conferred on the astronomical investigator, and is valued far more for the distinction than for the purse accompanying it. Before Barnard, but few American astronomers have succeeded in gaining the Lalande prize, among them Watson, Swift, Newcomb and Hall.

PLANS and specifications for a new system of water works for Santa Rosa have arrived. The new system is that of Wagner's steam well or underground reservoir system. A few months ago the city employed C. Monjeau, secretary of the Cincinnati Water Supply Company, to act as an expert. He came and reported the steam well system feasible. An election to bond the city to build the system will be called in the near future.

Industrial Notes.

THE oldest paper mill in the State is at Taylorville, Marin county. It was established in 1853, and is still in successful operation.

THE State Labor Commissioner recommends the establishment by the State of free employment offices in all cities of over 25,000 inhabitants.

THE steamship companies of this city employ 2036 men, receiving from \$150 to \$250 per month as captains, down to \$25 per month as stewards' assistants.

THE Telegraph avenue electric line, between Berkeley and Oakland, commenced operations on Wednesday. This is said to be the best equipped electric road in the State.

THE steamer Noyo left Fort Bragg Wednesday afternoon with another cigar-shaped raft of logs containing 1,500,000 feet of lumber. This is the fourth big raft huilt to be brought to San Francisco.

THE Tuhhs Cordage Co has discharged all its Chinese employees. They have gradually been putting white men and boys at work for some time past, and the entire rope works will be run in future without any Chinese.

A VERY large dynamo was put in at the power house of the Oakland, San Leandro and Haywards electric road this week. It is of 450 horsepower, and will be run in connection with the 500 horsepower engine to furnish electrical power for the entire system, including the Washington-street extension.

VINEGAR and pickle factories are increasing in this city. In 1891 there were six of them, with an output of 970,000 gallons of vinegar and 120,000 gallons of pickles, worth in all \$200,000. Now there are fourteen factories, turning out over 1,000,000 gallons of vinegar, 150,000 gallons of pickles, and the joint product is valued at \$250,000.

THE carmakers of this city are doing a fine business these days, and this is readily understood when the extension of the streetcar lines is remembered. The electric and cableroads of this city have all their cars made in this city, and in spite of the fact that one of the largest car-factories in the city was burned to the ground there has been a good increase in the output.

DURING the month of December, 1892, local corporations paid a total of \$432,750 in dividends, against \$582,250 for the same month in 1891. The banks paid \$73,500, insurance companies \$3500, gas companies \$66,000, water companies \$70,000, powder companies \$31,500, street railroad companies \$13,000, mining companies \$135,250 miscellaneous companies \$40,000.

THE outlook for the petroleum industry in California is highly encouraging. Such flattering oil prospects have been obtained in Kern, Humboldt and several other counties during the year as denote for this industry early enlargement. Our oil-producing territory covers an immense area, and although the deposits generally lie deep and are somewhat scattered they offer great inducements for the inauguration of new enterprises and the investment of capital.

THE steamer Tihuron, plying between San Francisco and Tihuron, Marin county, was burned at her dock in this city on Monday, just after the passengers had gone ashore. The entire upper works were destroyed, but the hull was saved. What is left of the vessel was towed around to Little Main street Thursday and the work of tearing away the remains of her upper works begun. The work of reconstruction will be pushed forward with all possible speed, but it will be at least three months before the vessel will be ready to take her place on the route across the bay. In the mean time the old steamer James Donohue will take the Tihuron's place.

THE Hibernia bank lent \$3,870,936 on city property in 1891 and \$4,384,815 in 1892. The German bank lent on city property \$2,322,265 in 1891 and \$2,520,091 in 1892. The Savings union lent \$1,704,787 in 1891 and \$2,087,235 in the city in 1892. The Humboldt bank lent \$734,556 on city real estate in 1891 and \$497,970 in 1892. The French bank lent \$549,500 in 1891 and \$441,260 in 1892. The Clay-street bank lent \$542,050 in 1891 and \$409,579 in 1892. The Security bank lent \$253,700 on city real estate in 1891 and \$366,975 in 1892. The most of the money of five of our savings banks is lent out on interior lands, while two of them also lend in Oregon and Washington.

FOLLOWING close upon the opening of the Lifeboat by the Salvation Army people another interesting department has been added to the organization in the shape of a bureau of employment at the corner of Sacramento and Kearney streets. At that place applications are received from the help-wanting public for every character of employe from longshoreman to expert accountant. Captain McFee who superintends the establishment, desires all who wish help to apply to the bureau where they will receive immediate attention free of charge. An industrial department will be opened on Grant avenue next week where mattresses, brooms and other articles will be manufactured.

THE Callistro Company was organized by women to work a deposit of material used as a silver polish. They built a factory and began sending callistro all over the coast. They finally bonded the property to some Chicago people and agreed to close down. A year ago the women left the directory and some men took their places, but the works have since remained idle. At the annual meeting this week the women voted their shares in such a way as to again resume control of the company. The new directors are as follows: Mrs. Clara F. Hamilton of Oakland, Mrs. E. P. Eells of this city, Mrs. E. P. Buckingham of Vacaville, Mrs. Samuel D. Mayer, Mrs. Henry Wetherbee, Mrs. N. C. Whitney and Mrs. Sarah H. Tompkins. Mrs. Hamilton was chosen president, Mrs. Eells, vice-president; Mrs. Mayer, secretary, and Mrs. Wetherbee, treasurer. It appeared from the treasurer's statement that the company is in debt \$27,000, amply secured by lands outside the callistro holdings. The works will be started up again at once and callistro be put upon the market.

Exaggerated Mining Reports.

SAN FRANCISCO, Jan. 2, 1893.

TO THE EDITOR: I have had a good deal to do with mines and mining business in my day and am, as I may say, somewhat familiar with matters thereto pertaining.

I have noticed during my long experience some peculiar characteristics of the miner that, I fear, have led to the use of the term "honest" as intended in an ironical sense, growing out of, probably, his vividness of imagination. It is human nature to him to be sanguine, and it is this sanguine temperament that leads him to deceive himself often in his firm belief that he has before him in his claim the coveted thousands, as the reward of his labors; and he is indignant that the would-be purchaser in his cool, calculating way does not accord with his honest belief in its merits.

It is a well known fact that he will, with a view to ascertain for his own satisfaction the value of his ore, instead of taking average samples, be certain to select the richest piece in the dump, and build his hopes on the result of the assay, thereby deceiving himself as to the true value of his ore; but the highest flights of imagination and romance is reserved for the amateur writers of reports on such mines.

The owner of the claim desiring to have a report on his property and not feeling able to pay the high fee of the professional scientifically educated engineer, calls in the amateur, the usually termed "practical man," who professes to ridicule what he terms the highfalutin engineer, and hases his own claims to be a judge of mines on the fact of his having worked in them himself, hence is practical in experience. With, of course, no knowledge of the laws of formations or the geological characteristics of the rock he is called upon to examine, his report is often a confused jumble of scientific terms most amusing to the initiated; but it reads well to the general public, which knows nothing of the subject.

The amateur, with a view to making a report pleasing to his employer and reconciling him to the fee for the examination, allows his imagination to indulge in the wildest flights, and the report vies with the most extravagant romances of the age. In his desire to give the mine a good "send off," he deceives the owner and makes the mine appear to be a veritable bonanza—not what it really is, but what the owner wishes it to be.

With this report in his pocket the owner betakes himself to the nearest city to sell or enlist capital and, on the strength of the report, contracts to pay the expert the would-be capitalists may select to make an examination of the property, for their security and satisfaction.

It is needless to say that in nearly every instance the report is adverse, and the sanguine owner is the poorer for the transaction; but in his persistent belief in the merits of his mine and the judgment of the "practical man," his faith remains unshaken, and he "cusses" the ignorance and prejudice of the capitalists' expert, as "one of those d—d scientific, 'edicated,' Freiburg fellers, who don't know a mine from a hole in the ground," and hints that "the feller" has a mine of his own to sell his employers.

A collection of mining romances in the shape of reports on mines, if published, would afford entertainment for readers of fiction unequalled by any modern publication. They would marvel at the power of imagination of the authors, while those who have a tendency to believe everything true that is printed would wonder why all this scare about the depletion of gold consequent upon shipments abroad, when the woods and rocks were full of it, only awaiting the taking. The attention of publishers is called to this hitherto neglected and unrivaled theme for gratifying the sufficed readers of tales of the wide and woolly West, who require a more stimulating literary tonic.

MINING SHARP.

Statistics of the Mineral Industry.

"The Mineral Industry: Its Statistics, Technology and Trade," is the title of the annual statistical supplement to the New York *Engineering and Mining Journal*, shortly to be issued. The work of collecting and publishing in the *Journal*, within a few days of the close of each year, reliable statistics of the mineral industry of the United States and other countries, whose products are valued at far more than \$2,000,000,000, has become so important that a large octavo volume will be issued in January, 1893, covering them.

It will treat each of the various subjects in the following general order: Describing the occurrence and character of deposits in which the minerals are found; the characteristics of the mineral; methods of treatment; cost of mining; characteristics of metal or other products; costs; uses; statistics of production; imports and exports from the earliest times; consumption, total and per capita; review of markets; prices; foreign production; imports, exports and consumption; technical articles by competent authorities giving the recent progress in each department of mining and metallurgy. The progress in the chemical industry will be given in expert reports covering the industry to the close of the present year in Europe and America. The subjects treated will include: Acids, aluminum, antimony, asbestos, asphaltum, bauxite, borax, brimstone, bromine, barytes, chemicals and chemical fertilizers, chromium, coal, cobalt, copper, corundum, flourspar, gold and silver, graphite, gypsum, iron and steel, iron ores, lead, manganese, mica, mineral paints, natural gas, nickel, petroleum, phosphates, platinum and platinum minerals, precious stones, pyrites, quicksilver, soda (natural), sulphur, sulphuric acid, tin, zinc, etc. The price of this volume is set at \$2.00, bound in paper, and \$2.50 in cloth.

In 1887 there were only 13 electric roads working throughout the entire country. There are now in the United States and Canada over 500, representing a capital of over \$200,000,000.

Mica.

How It Is Mined and Prepared for the Market.

The name mica is not that of a single mineral, but is a family cognomen which includes a number of varieties. With the outward attributes of the family we are all familiar, for under the common name of isinglass it forms a small part of the stock in trade of every householder. The family is one of some importance in mineralogical classification. All are shining members, and are alike in splitting into extremely thin leaves or plates; in being more or less transparent; in being highly elastic; and in having certain ingredients in common. There are seven well-defined minerals which lay claim to the family name, besides an extensive list of relatives which have been formed by alteration or exposure to air and water. The series runs from the compact, glistening mica found in granite and gneiss, through many gradations of hydrous micas, until we reach the ordinary soap-stones and clays. But the name properly stops when the mineral loses its glistening surfaces, for the Latin word *micare* (to shine) no longer applies. Our German friends call it glimmer, a name whose significance is readily seen.

The location of the quarries has been largely accidental. So far as I have been able to learn, the first one opened was the Sinkhole in Mitchell county, N. C. The spot was marked by the existence of trenches, many hundred feet long in the aggregate, and in places fully 20 feet deep. Large trees growing on the debris indicated that the workings were very ancient.

Then, as now, the mountaineers were largely guided in their search by the ancient workings. These were probably made by the aborigines and were also for the purpose of obtaining mica. The imprint of their stone implements may still be seen in the decomposed stuff at the sides of the opening. What these people used the mica for is still problematical. Large plates of it have been found in the mounds of Eastern Tennessee, and would indicate that it had domestic application, or was used for personal decoration. The mica is seldom prepared for market at the quarry, but is taken to a conveniently located glasshouse. This generally means a transportation of several miles. Frequently the quarries are on steep mountain sides, and are only connected with the outside world by the roughest sort of trails. In this case, the mica is "packed" down the mountain on the backs of men to the wagon road in the valley below. At the glasshouse, the mica is put into shape for shipment. The blocks vary greatly in size. One from the Wiseman quarry, near Spruce Pine, is reported to have been six feet long by three wide. Pieces a yard in diameter have been obtained at the Ray quarry, in Yancey county, and similarly large plates have been found in Siberia, but these are exceptional. The average size of a block is a little larger than the page of a magazine, and is generally less than six inches in thickness. It separates very readily into sheets parallel to the base of the prism. It is estimated that this cleavage may be carried so far that it would take three hundred thousand of the mica plates to make an inch. It is needless to say, however, that such a thickness is not suitable for use in stoves and furnaces. The mica is generally split into plates varying from about one-eighth to one-sixty-fourth of an inch in thickness. In preparing these plates for market, the first step is to cut them into suitable sizes. Women are employed in this work, and do it better than men. The cutter sits on a special bench which is provided with a huge pair of shears, one leg of which is firmly fixed to the bench itself, while the movable leg is within convenient grasp. It is requisite that the shears be sharp and true, for otherwise they will tear the mica. The patterns according to which the mica is cut are arranged in a case near at hand. Generally they are simple rectangles, varying in size from about four square inches to eighty.

The cutter selects the pattern which will cut to the best advantage, lays it on the sheet of mica, and then, holding the two firmly together, trims off the edges of the mica to make it correspond with the pattern. When the cutter completes her task, she has all the mica piled away in little bundles under their corresponding patterns, while the scrap falls in a glistening heap on the floor. The cleaning process comes next. The cleaner must examine each sheet of cut mica by holding it up between her eyes and the light. If there be any imperfections, they must be removed by stripping off the offending layers of mica until a clear sheet remains. The cleaning is done by means of a sharp pen-knife—and considerable discretion. It is quite easy to tear away the entire sheet and have nothing left for one's trouble. Both the cutting and cleaning are tiresome routine operations, yet there is a certain fascination about tearing the mica to pieces that few have philosophy enough to resist. Finally, the cut and cleaned mica is put in pound packages, and is ready for market. There is an enormous waste in the process of preparation. One hundred pounds of block mica will scarcely yield more than fifteen pounds of cut mica, and sometimes it is even less. The proportion varies, of course, with different localities.

The chief use of cut mica is in stoves, and its comparative cheapness has made possible the luminous—not to say artistic—wonders which constitute the latest and most cheerful creations of the stove men. The sheets are also used in the peep-holes of smelting furnaces, in lanterns, in shades, and in the port-holes on board naval vessels, where the vibrations would soon demolish less elastic glass. Mica is an excellent nonconductor, and of recent years has been cut to some extent into narrow strips for use in the construction of dynamos.

The scrap mica was formerly thrown away, with the exception of a small quantity used as a lubricating material, but it has recently found a market in several new directions. Old waste heaps are being bought up, for a few dollars a ton, and their contents cleaned by being passed through a big mill. This is simply a rotating cylinder of coarse wire screen with its axis slightly inclined to the horizontal. The scrap is fed into the upper end of the cylinder, and slowly

discharges itself from the lower end. As it makes its way from end to end, the sand and trash fall through the meshes of the screen.

The cleaned scrap is then ground into a coarse powder and distributed to the various industries requiring it. Large quantities are used in the manufacture of wall paper. The mica produces a sparkling surface which is thought to be decorative, but at best the effect is somewhat bizarre. Considerable amounts are used to produce the snow effects on Christmas cards, and in stage scenery and other tinsel; while smaller packages, under the name of diamond dust, are sold as powder for the hair. Much of the ground mica is sent to France, and this, oddly enough, when the East Indian sheet mica is pressing our own pretty heavily in the home market. The Latin world used the mica dust to strew over the Circus Maximus, while mediæval Europe knew the golden and silver scales as cat-gold and cat-silver.—C. Hanford Henderson in *Popular Science Monthly*.

Artesian Wells.

One of the most remarkable features of California and one that strikes the visitor with wonder is the artesian wells that are seen in various parts of the State. And it certainly is good ground for wonder when one sees a pipe sunk into the bowels of the earth, from which pours without ceasing or diminution a flood of a million and a half or two million and a half gallons daily. Artesian wells have been successfully sunk in many parts of the State.

They are found in the Santa Clara valley, in the San Joaquin and in the counties of the far south. But it is unquestionable that the most remarkable development in this direction has been in what is known as the artesian belt of Kern and Tulare counties. When it is known that single wells, sunk at a cost of from \$1,000 to \$2,000, afford a flow of water sufficient to irrigate an entire section of land, a faint idea can be formed of the vast importance and the illimitable possibilities presented.

There are artesian wells in some localities which flow as high as two and a half million gallons daily. This is sufficient to irrigate 640 acres of land. When it is known that without this water the land is practically valueless, and worth at the most \$2 or \$3 an acre, while with it the same land is fully equal to that for which \$100 or \$200 an acre is asked elsewhere, then an idea may be formed of the vast importance and value of the artesian system.

There are many advantages in a farmer owning his own source of water supply instead of having to depend upon ditches or canals owned by others or by incorporated companies. These advantages need not be discussed here, but every irrigator is fully cognizant of them. Consequently the intending settler should be guided by the experience of others, and if he can buy land at a moderate rate within the limits of the artesian belt he cannot do better than locate there, and either singly or in a conjunction with some one or two neighbors, sink a well.

It has been abundantly proved that within certain quite well defined limits, there is no such thing as failure to strike a good flow, while by a few settlers combining, the cost to each may be made very small, and at the same time the result will be in the highest degree satisfactory.—Irrigation Age.

The Game Law.

When the game law was amended the law used was so ambiguous that a great many construed it to mean that game used for food could be killed at any season of the year. Of course it was never intended that such a license should be granted.

Crittenden Robinson, president of the Sportsmen's Association, addressed an inquiry to the Attorney-General and received in reply the following:

"Yours of the 26th ult. received. I agree with you in the construction of game laws: Section 626 Penal Code, Statutes of 1891, page 472. The killing of game is not *malum in se* or wrong of itself, but is wrong only when, for the public good, it is prohibited by statute. The best of citizens, through lack of acquaintance with law, are liable to violate it.

"Under the eighth paragraph of the statute, it is a misdemeanor to kill any of the birds or other animals therein mentioned at any time of the year, whether during the open or closed season, 'unless the carcass of such animal or bird is used or preserved by the person taking or slaying it, or is sold for food.'

"This was enacted to prevent the wanton and wasteful destruction of game by persons who are not in pursuit of food either for themselves or for others, but who kill for mere amusement or for the hides of animals. The law is a good one and should be rigidly enforced, for game is becoming scarce in the State, and the food supply of a country cannot be too great. I do not think any one in this office ever meant to express views differing from these."

THE Pacific Reduction Works of Nevada city, have lately been purchased from the Citizen's Bank of that city, by Messrs. Hall, Black, J. and J. G. Northey. For a long time the works had been held on a mortgage from A. Maltman. Under the present management the works have been running successfully for the past three months. Much of the sulphurets formerly shipped to Salt Lake, Portland, and San Francisco are now treated here. The large furnace is run to its full capacity, handling from four to five tons of concentrates per 24 hours. Returns for both gold and silver are made and prove satisfactory to the mining companies and the management of the chlorination works. The value of the work done aggregates \$10,000 a month. At present the chemical shops and settling reservoirs are some distance from the furnaces. These, however, will shortly be moved and put in close connection with the roasting plant and thus greatly facilitate the handling of the concentrates.

J. H. MORTON is superintendent of the Mammoth mine, Old Diggings, Shasta county.

Cube and Square Roots.

For the Boys.

TO THE EDITOR:—In the *Scientific American* supplement of September 6, 1890, Prof. H. A. Wood, of Stevens' School, gives a new method of extracting the cube root of a number, as follows:

OPERATION.

$$\begin{array}{r} 11^3 = 121 \ 1,412,467,848 \\ \underline{1167} \\ 3 \ 3367 \\ \underline{1122, \text{ cube root.}} \end{array}$$

In this example the cube root of the first two periods is readily found to be 11, which we take as the trial root. Dividing its square into the given power to four terms, since the root contains four figures, we obtain the quotient 1167. To this quotient adding twice the trial root, regarded as hundreds, and dividing by 3, gives 1122, the correct root.

NOTE. 1.—If there is a remainder, after dividing by 3, it is disregarded.

2. The first term of the root is determined by inspection. The second term of the trial root, if not readily apparent, may be found by trial, or as the entire root is found above, when two figures are used as the trial root. The first two terms of the quotient must not differ by more than a unit or two from the trial root.

SOLUTION OF SECOND EXAMPLE.

$$\begin{array}{r} 15^3 = 225 \ 3,341,362,375 \\ \underline{1485} \\ 30 \\ \underline{3 \ 4485} \\ 1495, \text{ cube root.} \end{array}$$

In this example, taking 14 for the trial root, the first two terms of the root being then 17, shows that 14 is too small. Taking 16 as the trial root, the quotient then being 13, shows that 16 is too great. By this means the second term of the trial root may be found, or the first two terms may be extracted by the usual method of extracting cube root.

3. Required the cube root of 2515, correct to 7 decimals.

$$\begin{array}{r} 14^3 = 196 \ 2515.0 \\ \underline{12.8} \\ 28 \\ \underline{3 \ 40.8} \\ 13 \ 6, \text{ 1st ap. root.} \\ 13 \ 6^3 = 184.96 \ 2515.00000 \\ \underline{13 \ 5975346} \\ 27.2 \\ \underline{3 \ 40.7975346} \\ 13.5991782, \text{ cube root correct to 9 figures.} \end{array}$$

4. Required the cube root of 20. The nearest cube to 20 is 3³.

$$\begin{array}{r} 3^3 = 9 \ 20.0 \\ \underline{2.2} \\ 6. \\ \underline{3 \ 8.2} \\ 2 \ 7, \text{ 1st T. R.} \\ 2 \ 7^3 = 7.29 \ 20.000 \\ \underline{2 \ 743} \\ 54 \\ \underline{3 \ 8.143} \\ 2.714, \text{ 1st ap. cube root.} \\ 2.714^3 = 7.365796 \ 20.000000 \\ \underline{2 \ 7152534} \\ 5 \ 428 \\ \underline{3 \ 8.1432534} \\ 2.7144178, \text{ 2d. ap. cube root.} \end{array}$$

From these examples we deduce the following

RULE.

I. Having separated the number into periods of three figures each, counting from the right, divide by the square of the nearest root of the first period, or of the first two periods; the nearest root is the trial root.

II. To the quotient obtained add twice the trial root and divide by 3. This gives the root or first approximation.

III. By using the first approximate root as a new trial root and proceeding as before, a nearer approximation is obtained, which process may be repeated until the root has been extracted or the approximation carried as far as desired.

REMARK.—In example 4 it will be observed that the second term, or first two figures of the root, were obtained by using for trial root the root of the first period. Using, in like manner, these two terms for trial root, we obtained

four terms of the root, and these four terms of the trial root gave seven figures of the root correct. In that example the last figure should be 7. Should we take these eight figures for trial root, we should obtain at least 15 figures of the root correct. In general, by carrying the division to twice the number of places used in the division, the last figure will be correct, or but a unit or two out of the way.

Prof. Wood gives an algebraical demonstration of the principle used in his elegant method, for which I refer the curious to the original article.

I find that an analogous procedure may be applied to square root. Let us try it:

$$\begin{array}{r} 95 \ 93 \ 12,25 \\ \underline{980} \\ 95 \\ \underline{2 \ 1930} \\ 965, \text{ square root.} \end{array}$$

Again:

$$\begin{array}{r} 4.5 \ 20.0 \\ \underline{4 \ 44} \\ 4.5 \\ \underline{2 \ 8 \ 94} \\ 4 \ 47, \text{ first approximation.} \\ 4 \ 47 \ 20 \ 00 \\ \underline{4 \ 474} \\ 4 \ 47 \\ \underline{2 \ 8 \ 944} \\ 4 \ 472, \text{ second approximation.} \end{array}$$

I find these methods easier to remember than those of the schoolbooks; their chief utility, including the subject of my previous article on squares and roots, lies perhaps in their application to the extension of the engineers' tables of squares, cubes and roots to numbers not therein given.

C. H. AARON.

Cheap Engineers and Expensive Lawyers.

We frequently receive very decided expressions of opinion from those whose experience makes them the best judges against the old-fashioned, short-sighted, penny-wise and pound-foolish policy of employing the cheapest possible service in engaging professional engineers, while, when it comes to lawyers' fees and presidents' and managers' salaries, large sums are paid without hesitation. Any one who will take the trouble to find out how much time must be spent and what the amount and nature of the studies are to become a good engineer, and then compare this with that required to become a good lawyer, cannot fail to notice how much greater the former is. Moreover in the engineering profession one must continue to study and keep abreast with the rapid progress made in engineering, while in the lawyers' profession the term "progress" hardly exists. Of the four professions, medical, theological law and engineering, the latter is certainly the one in which one's reputation depends entirely on ability, that is, the one which requires the most conscientious work in order to gain and keep a good reputation. When an engineer is ignorant, and makes mistakes in building a bridge, machine or a mining plant, for instance, which thereby breaks down, there is no question where the fault lies and whose it was, and, what is worse, the lives of innocent victims are often at stake. Of all professional men, therefore, the engineer must work, study and practice in the most thorough and conscientious manner. We should, therefore, be selected with the greatest possible care, and receive the most liberal remuneration. The man who will take the greatest care in engaging a physician, regardless of cost, will go to his factory and engage cheap and incompetent professional engineers, and practically intrust the success of his manufactured products or constructions to their care, and then wonder why other manufacturers who pay for able talent are more successful. Some companies pride themselves, and with right, on the professional engineering talent which they employ and can retain by paying properly for it, but there still appears to be many who stick to the short-sighted policy of under-paying the one in whom the success of their products, to a great extent, lies.—The Electrical World.

THE late Wm. A. Aldrich of Oakland was a man who was interested in many industrial enterprises in that city and in San Francisco. He left an estate of about \$600,000 in value, which has just been appraised by Thomas Prather, Albert Miller and W. E. Miller, three gentlemen well qualified for their task. The value of the shares in many of the companies, as stated by the appraisers, is of general interest. Among other stock held by the late Mr. Aldrich were 5421 shares of stock in the South Feather Water and Union Mining Company, appraised at \$100 per share; 435 shares stock Oakland Bank of Savings, valued at \$75 per share; 810 shares stock Merced Security Savings Bank, at \$45 per share; 1100 shares of stock Savings and Loan Society of San Francisco, \$100 per share; 300 shares stock Bank of California, valued at \$262.50 per share; 1250 shares stock Pacific Power Company of San Francisco, valued at \$37 per share; 200 shares San Francisco Gas Light Company, at \$70 a share; 534 shares in Great Western Quicksilver Mining Company, valued at \$5 per share; 50 shares in California Powder Works, at \$150 per share; 550 shares in San Francisco Tool Company, \$40 per share; 171 shares Germania Lead Works, San Francisco, \$50 per share; 10 shares Pacific Surety Company, at \$102.50 per share; 100 shares Presidio and Ferries Railroad Company, San Francisco, at \$25 per share; 226

shares in Paraffine Paint Company, San Francisco, at \$0.75 per share; 1000 shares in Alaska Coal Company, at \$1.50 per share; seven first mortgage bonds of the Consolidated Piedmont Cable Company of Oakland, full value \$1000 each, appraised at \$900 each.

Gold Mining in the Southern States.

Up to the time of the discovery of gold in California, this precious metal was mined in the South Atlantic States of Virginia, the two Carolinas, Georgia, Alabama. The annual product was not large enough to give the United States a prominent place in the ranks of the gold countries, but nevertheless it had a place. The United States mint was established in Philadelphia in 1792, but the Carolina and Georgia mines were considered of sufficient importance to justify additional coinage facilities near to the sources of supply, and consequently a branch mint was set up at Charlotte, N. C., in 1837, and another at Dahlonega, Ga., in 1838. The New Orleans mint was also established in 1838, with the object of coining the silver received in trade from Mexico.

According to the mint records, as given in the official report of the superintendent, the total product of gold mined in the limits of the United States from the establishing of the mint to the discovery of gold in California, a period of 56 years, from 1792 to 1848, was \$24,536,000, less than half a million a year. After the enormous richness of the California deposits became known, there was a wild rush for the Pacific slope, and mines along the Atlantic ranges of foothills were much neglected, though not entirely abandoned. These Atlantic slope sources of gold supply are in the hills along the eastern base of the Blue Ridge or Appalachian chain of mountains. In Alabama, where the range loses its continuous and ridge-like forms, and breaks into rugged knobs and rocky hills, the gold deposits extend around their southwestern slopes. The gold originally occurred in veins and seams of quartz, associated with granite, slates, mica and talcose rocks, the ordinary accompaniments of gold-bearing quartz. Where the material carrying gold has been decayed by the weather, or broken down by physical forces, the gold is found in the gravel in the beds of streams, as in the case of the California placers.

These mines of the Appalachian range are still worked, and the introduction of improved processes has considerably increased the production. A recent mint report shows a result which, while it is far from realizing any dreams of fabulous wealth, shows that there is gold enough to be worth working for in these southern States. It is as follows for the year 1889:

States.	Gold Produced.
Virginia.....	\$ 4,100 00
North Carolina.....	146,295 00
South Carolina.....	46,852 00
Georgia.....	107,605 00
Alabama.....	2,589 00

Total.....\$317,433 00

This is not up to the average yearly production of these States in the ante-California period, but it all proves that the southern States, in addition to their other rich resources, are also producers of the most precious of the metals in commercial and financial use.—New Orleans Picayune.

The Mica Mines of Nellore.

Dr. Warth, officiating superintendent of the Central Museum, London, has written a most interesting report upon Mr. E. H. Sargent's mica mine near Inikurti, a place 19 miles from Nellore. Mica is the talc of commerce, although scientifically speaking the latter is quite a distinct mineral. Some idea of its value may be gathered from the following approximate rule for calculating the price of ready-cut selected rectangular pieces in London. One pound weight costs as many times twopence as each single piece has square inches surface. This equation holds good between 10 and 100 square inches. Below these limits the prices are smaller and become finally nil; above these limits they are higher and would end in fancy prices. Although Mr. Sargent's mine has only reached a depth of 60 feet, no less than 20 tons of pure ready-cut mica have been extracted during the past two years. It appears that the first indication for this deposit was a ridge of quartz which stood 8 feet above the surface of the plain. Then Mr. Sargent found old excavations on the west side of the ridge, which he followed up. At a distance of about ten miles to the south Dr. Warth found quite a group of more or less successful mica mines in similar rocks near the village of Utkur. The mica was associated with the same white quartz and whitish feldspar. There were also the same accessory minerals, garnet and tourmaline. One mine, called Sukbagini (black stained mine) produces mica which is stained black and brown through the spread of manganese ore and iron between the planes of cleavage. Some slabs of very clean surface, without any cracks whatever, 27 inches by 32 inches, were in store. The price of these would have been fabulous if they had not been black. We further learn from Dr. Warth's report that the sorting of the mica is very important for the trade. A large quantity of the mica is thrown away at the pit, where the waste heaps glisten in the sun. Of the mica brought to Mr. Sargent's stores at Inikurti, only about 23 per cent is finally selected for the trade. Everything else is thrown away, being either cracked, not sufficiently transparent, ripple-marked, or too small. The smallest limit of rectangular size is 2 inches by 2 inches, but such small sizes are at present very cheap, as Bengal exports too much of it. The pieces are all cut according to rectangular patterns. Pieces of the same pattern are then tied in bundles and so sent to London.

Mechanical Progress.

The Future of Machinery.

Advanced ideas in any sphere of human endeavor are seldom received with favor, and the artisan or thinker, or whatever he may be, who presumes to enlighten humanity upon truths which it is unprepared to receive, is very apt to be treated with ostracism or contumely for his pains. But as all progress is made through sacrifice of some kind or other, we may rest assured that the truth, be it social, economical or otherwise, will force its way despite all obstacles to a triumphant victory.

The truth of the foregoing, adds the *Age of Steel*, finds a splendid exemplification in the history of mechanical progression. The toiling thousands found it difficult to believe that the new innovations of machinery in their various occupations would not leave them eventually without anything to do, and in some cases there were those who strove to throw legislative stumbling-blocks and other obstacles in the way of the unwelcome competitor of manual labor. With the lapse of years, however, the mists of ignorance and prejudice have cleared away, and with the increase of wisdom garnered from observation and practical experience, the grimy-faced toilers in forge and mine and factory have learned to look upon machinery as the friendly ally rather than as the enemy of labor. They have begun to see that the forces of production, however multiplied or improved, can never do any harm to mankind unless, by the mal-administration of economic laws, they be turned from the service of the many to the exclusive benefit of the few.

With this truth fully grasped and comprehended, the tendency of economists at the present time is to shape the forces of production and distribution that this humane view of machinery in its relation to humanity may find a full and complete realization. No man will ever starve because there is too much to eat; and if all do not get what belongs to them, it will not be because there is not enough, but for the reason that the product of their labor has been unfairly administered in the process of distribution; so that whatever men suffer to-day in an economic way, they have ceased to place the blame upon machinery, and have transferred it to the men who manipulate it to the advantage of themselves at the expense of their fellows. Instead of retarding mechanical progress, we are predicting for it an immeasurably wider field of activity, and are speculating upon its application to uses which a short time ago we would have declared a man insane for daring to attempt. We are beginning to look upon machinery, in short, as a means by which man can realize his highest dignity, in mustering it into our service in those fields of industry where the labor we are called upon to do is brutalizing or otherwise injurious to the physical or moral constitution of man. Hence it is that in silent rooms and in lonely garrets, busy minds are to-day painfully struggling to contrive mechanical appliances that will do away with all manual labor that overtaxes or devitalizes human energy in its performance. The mechanical ideal has been shifted to a loftier plane, so that it is now intended that eventually all unintellectual labor, all monotonous, dull labor, all labor that deals with dreadful things and involves unpleasant conditions, must be done by machinery. Machinery must work for us in coal mines, do all sanitary services, be the stoker of steamers, clean the streets and do all work that is tedious, filthy or extremely distressing. There is no doubt but that this is the future of machinery, and its realization, however far removed, will mark an epoch the most brilliant by far in the history of civilization. Mechanical News.

Splicing Woven Belts.

Everyone, says the *Textile Recorder*, who has had any experience in the splicing of that class of woven belts which are now in such extensive use, is fully aware of the great difficulty which exists when it is necessary to piece them. The most common practice is to join the two ends by malleable iron fasteners, which are fitted with screwed shanks on which nuts can be placed. In what is, perhaps, the most successful of these arrangements, the ends are turned up and bolted together in this way. But it is obvious that, whatever may be the merits of such an arrangement, it is calculated to throw the belt out of balance while it is running, owing to the addition of weight at one point. This has not been objected to hitherto because of the general effectiveness of the fastening, but it is quite clear that a method which, while equally effective, is free from

the fault named, will be of considerable value. Such a method has been introduced by Messrs. Fenton, of New Lanark, who proceed by splitting the ends of the belts by suitable means. In lieu of this the belt may be woven in layers at the point where it is desired to join it, but this, of course, implies a foreknowledge of the length of belt to be required. Having obtained the necessary division, however, by any means, two of the four plies or tongues formed are cut away, and the two ends are then fitted into each other. The finished joint is of practically the same thickness and weight as the rest of the belt. By means of suitable cement or glue a perfect union is obtained, but it may be made more secure by the employment of laces, wire threads, or rivets. It is claimed that the belt so pieced is not only as strong as the joining as any belt pieced in the ordinary method, but that, being of an even thickness throughout, it is in a truer balance, which in high-speed machinery is a matter of some importance. The perfect interlocking of the two ends enables a secure fastening to take place, which renders the belt equal in strength at this point to any other portion of it.

Steel or Iron for Tin and Zinc Coating.

The *Metal Worker*, in speaking of the "pin-holes" in tinned andterne plates, and scaling of the zinc coating on galvanized sheets and pipes, says: Our readers are generally familiar with the argument about pin-holes, and know that the source of the difficulty has never been satisfactorily determined. One of the many causes to which the trouble was ascribed was the use of steel in the place of wrought iron. The question was argued in various ways, some saying that foreign matter in the steel interfered with the pickling and prevented the perfect coating of the plates, so that in places there was only a thin skin of tin unattached to the plate, and when this was abraded corrosion rapidly ensued. Others said that the pickling acid nested in the particles of carbonaceous scale, and kept up the work of corrosion after the plate was coated. One of the most plausible suggestions, however, was that the difficulty lay with the texture of the steel itself, that it was too fine grained a material in comparison with iron, and the surface was so hard and smooth that there was no opportunity for that superficial alloying which is supposed, rightly or wrongly, to constitute the bond between the black plate and the coating. The fibrous nature of iron, and the somewhat roughened surface, lets the tin soak in, if such an expression may be allowed, and makes a firm fastening with the base.

Whether this is the explanation of the pin-hole difficulty in tin-plates has not been definitely decided; but that there is trouble, not only with tin-plates, but with other forms of coated sheet metal that did not exist 20 years ago, is a complaint that reaches us from many sources. Speaking of the durability of tin-plates it is a common saying that in the old days unpainted bright plates on roofs in certain parts of the country lasted a quarter of a century and more without showing signs of rust. In the same dry climate, if the experiment were repeated to-day with the modern plates of leaving them unpainted, destruction would soon result. A corresponding complaint is made respecting galvanized iron of the present day, and the hypothesis is stated that the trouble is due to the use of steel, to which the zinc does not adhere as tenaciously as it did formerly to the iron. In proof of this it is pointed out that even the best coated galvanized "iron" will peel off sharply bent, and in furnace pipes and in other places where subjected to heat, the zinc will scale in a way it did not use to scale. We are told that the galvanized iron of the olden time was an excellent material for water tanks and would last an almost indefinite period, while if the modern product is used for the purpose it will often corrode almost immediately. And right here we might mention a curious thing about this whole enigma, and that is that there is no certainty about the matter. In some cases the galvanized iron, or tin-plates, as the case may be, will wear excellently, while the very next plate will corrode with surprising rapidity. The same complaint is made about the galvanized range boilers which are made of steel. Some of them show no traces of rust, while others will pit right through in a very short time. It is well known that enameled ironware requires a high grade of soft iron, and so far as we know, the enameled coating has not been successfully applied to steel plates.

The solution of this problem, however, should engage the earnest attention of the trade, and the quicker a new process is introduced the better it will be for the manufacturers and jobbers and for the whole sheet-metal working trade.

Scientific Progress.

Science in Medicine.

The recent address at St. George's, London was delivered by Dr. Bowles, of Folkestone. The lecturer commenced by welcoming the new students, and urging them all to preserve the tradition that "a St. George's man is expected at all times and under all circumstances to be a gentleman." The apprenticeship system was announced to be dead—defeated by the rapid march of science. This led to the main subject of the address, "the application of physics to physic." It was pointed out that all changes occurring in physiological and pathological processes formerly supposed to depend on that unknown quantity, "vital force," were really nothing more than the action of the recognized forces of nature on the organs and structures of the body. Coughing, sneezing, snoring, etc., were all shown to have immediate origin in physical conditions. Surgery is the proper application of the laws of physics; injured parts and broken limbs are kept at rest, dislocated parts are placed in their natural positions, redundancies are removed, and natural deficiencies often well supplied; crooked paths are made straight, and blocked and narrowed ones made patent; stiffened joints are made to move, crooked limbs put into shape, eyes are made to see that would not, and ears to hear that could not.

Surgery is a department of physics—a physical art. Medicine, formerly the region of the unknown and the happy hunting ground of quacks, is rapidly following in the same lines. The so-called practical man and the believer in dogmas and nostrums are rapidly giving way to minds trained in the laws of physics. Physiology, Medicine's forerunner and its handmaid, is steadily, step by step, and without prejudice elucidating the ways and doings of animal life. By instruments of the most elaborate and delicate nature, by patient and continuous observation, by anatomical and histological searchings, and by the application of the laws of gravitation, chemistry, heat, light and electricity, always by ways and means connected with physics, we are getting to understand better and more surely the movements and functions of respiration, of circulation and digestion, of secretion and excretion, and finally we hope to understand the most subtle and mysterious of all functions—the operation of the nervous system.

The lecturer then reviewed the rapid progress made in late years in the studies on which the medical art is based. Schroeder in Germany, and Pasteur in France, by their investigations on fermentation and putrefaction, and Chauveau on the particular nature of contagia, have opened up an entirely new world. We have now not only to study the causes as well as the changes of the disease in the body, but also the doings of the bacteria outside the body and within it. In view of the more scientific methods of modern pharmacology and therapeutics, students were cautioned against long and complicated prescriptions. Not a single drug ought to enter the body except under clear intention of what object it is to fulfill there. Compounds may be good cookery, but do not form scientific medicine. Finally students were warned against mistaken views of materialism. The students of the physical and biological sciences are emphatically the servants of nature. The man of science interprets the physical laws, and equally with the teacher of religion tells us of the greatness and grandeur of the Creator. Every discovery of the scientist can only tend to increase our wonder at the omniscience of the ways of God.

FACIAL EXPRESSIONS.—A close observer of the facial expressions of different individuals, says the *Optician*, will find a great variety in their delineation, based almost entirely upon the direction of the axis of vision. In children this axis is almost constantly parallel, producing the impression of thoughtlessness or the childish, innocent look. With increasing intelligence, the eyes lose the parallelism by being fixed upon objects of investigation. All affections of the mind are now manifested by certain motions and positions of the eyes, which become more and more convergent. The lurking look of the criminal on trial, the watchful scrutiny of the over-suspicious, the lustful look of the libertine, the piercing glance of anger, the rude gaze of the ruffian, and the fearful glare of the maniac, all are modifications of the same act, produced by an increasing convergency of the axis of the eyes. The eyes of a frightened person diverge; the wish to be far away from the place of danger causes the dilating of the pupils and the opening of the eyelids. In old age the axis of

vision again becomes parallel. The passions of former years are calmed, and the mind, in a contemplative mood, is now diverted upon its future distant home. At last the eye dies in the absolute parallelism of the axis of vision.

Glazing as a Science.

Glazing is being exploited as a science by Mr. Edward Atkinson, who in a recent talk told most interestingly of certain experiments he has conducted and experiences he has had in relation to the quantity, quality and usefulness of light as received through different sorts of glass.

At a meeting of the British Association, said Mr. Atkinson, an explanation was given of the Fresnel lens for transmitting light in one beam horizontally. Now, by reversion, a glass apparatus has been made to serve as a diffuser of light. You will be surprised to know that the amount of light that is absorbed by ribbed glass is ten per cent, and by clear glass is eight per cent; that there is only two per cent difference in the obstruction of light between a double-thick German clear and a fine-ribbed plate of the same thickness.

Now, through plain glass you get no diffusion; your light falls directly on the floor, and the clear sunlight falls on your looms or frames, if you are at work in a factory, making dark shadows; while with the ribbed glasses you get a diffusion through the room without a glare; you need no window shades and you have no dark shadow. Then, in the practical use of light, you will get a vast deal more with that ribbed glass without window shades than you will with the clear glass with the window shades which you must have on a south side.

An inventor, continued Mr. Atkinson, has worked on my theory of window glass. He has applied this idea to a conical glass, which is put under the arc light; with this he has done away with the glare and destroyed the shadow. You may have daylight from an arc light in your mills without the shadow and without the glare. The dispersion of light through the ribbed glass is relatively 64 per cent in horizontal planes to 0 per cent in plain glass.

THE SCIENCE OF METALLURGY.—We are glad to see that in the United States, as in Great Britain, the old idea that metallurgy is but a corner of engineering territory is gradually being exploded. In Germany, France, and Belgium the science of working metals has very properly long been severed from the art of the engineer, and with beneficial results to the metallurgical industries. In England the almost superstitious notion that a metallurgist must needs be an engineer, and vice versa, has long prevailed; and it is only comparatively recently that the erroneous impression has evinced signs of dissipation. To-day, even, there are numerous iron and steel masters whose hebdomadal dose of technical literature is derived solely from the old-fashioned engineering journals, which touch a metallurgical matter perhaps once a month, and even then consider that the space appropriated to what they are pleased to term "an out-of-the-way branch of engineering" is practically wasted. How can iron and steel masters possibly keep abreast of the times with respect to trade information, and of the technical advances which are constantly being made in their industry, when they see nothing of the literature which they ought to study—when they neglect the journals which are specially devoted to their interests, for the sake of periodicals which really do not profess to cater for them? "The science of metallurgy"—lately said Mr. Thomas Turner, the president of the South Staffordshire Institute of Iron and Steel Works Managers—"the science of metallurgy is of sufficient importance to the country at large, is itself established on a sufficiently firm and separate basis, and, I may add, offers sufficient pecuniary return to those who devote themselves to it, to warrant its separate existence in our leading institutions free from all restrictions or leading strings." Mr. Turner has, to quote a characteristic expression of Bluff King Hal's, "taken the right sow by the ear."—Iron.

PROFITS OF COPPER MINING.—The Calumet and Hecla, the great copper mine, has declared \$2,000,000 in dividends for the present year this making a total dividend paid to date of \$38,850,000. Assessments have been levied to the amount of \$1,200,000, and the capital stock is \$2,500,000. To those who have held the stock from the time the mine first began to yield a profit, the gain has been enormous, but there are comparatively few shares so held. Much of the stock has been purchased at a high figure, and upon its present selling price it pays only about 7 per cent.

JOSHUA HENDY MACHINE WORKS,

NO. 51 FREMONT STREET, SAN FRANCISCO, CAL.

BUILDERS OF

"Sensible" Horse-Power Hoisting Whims.

(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, on hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake wheels at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and sheaves, 1400 lbs.
Circulars giving Capacities and Prices furnished on application.

BALDWIN LOCOMOTIVE WORKS.

ANNUAL CAPACITY 1000. ESTABLISHED 1831.

LOCOMOTIVE ENGINES!

Adapted to every variety of service, and built accurately to standard gauge and templates. Like parts of different engines of same class perfectly interchangeable.

Broad and Narrow Gauge Locomotives, Mine Locomotives by Steam or Compressed Air, Plantation Locomotives, Noiseless Motors for Street Railways, Furnace Locomotives, etc.

COMPOUND LOCOMOTIVES

GEO. H. STROUD.

Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED 1860

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, San Francisco.

RUPTURE, PILES and all Rectal Diseases POSITIVELY CURED, in from 30 to 60 days, without OPERATION OR DETENTION FROM BUSINESS. Also ALL NERVOUS, SKIN, BLOOD, PRIVATE AND CHRONIC DISEASES OF BOTH SEXES, STRUCTURE AND URINARY TROUBLES CURED. No charge unless cure is effected. Consultation free. Call or address for pamphlet, DR. PORTERFIELD & LOSEY, 888 Market Street, San Francisco, Cal.

Useful Information.

A Little Knowledge is a Dangerous Thing.

Mechanical, civil and other engineers who are not electricians cannot have the fact too strongly impressed upon them that work or power measured or represented in electrical terms is as much dependent on the volts as it is on the amperes, precisely as foot pounds of work depend on the feet as well as on the pounds. Amperes by themselves do not, therefore, represent any definite amount of energy unless accompanied by the volts measured between the two points of a circuit at which the energy is to be measured. Through the extended use of constant potential circuits it has become the habit of many to assume that the voltage is constant in all parts of the circuit and its measurement is, therefore, often dispensed with. It should be remembered that in all such cases the results are correct only to the degree to which the voltage may be assumed to be constant; that is, if the whole voltage may be 10 per cent out, the power calculated from the amperes and the assumed voltage will be uncertain to within 10 per cent. Only in incandescent lighting circuits, where the voltage is kept constant, through extreme care, at the consumer's end of the line, can it be assumed as remaining the same. On power circuits it may, and generally does, vary very materially. There are, moreover, many conditions which influence the voltage at the receiving end of a line—as, for instance, the speed of the generator, the resistances of the line, the fuses, instruments, etc., the current on the line (which, in turn, again often affects the speed and voltage of the generator), etc.—so that, to assume the voltage at the poles of a distant motor, while running, to be that engraved by the makers on the face plate of the generator, is almost as bad as assuming the boiler pressure in a steam engine test to be that for which the makers claim it to have been built. Unless the generator is very nicely over-compounded to suit that particular line, and unless its speed remains constant for all loads, even when a heavy load is placed on suddenly, it may cause very material errors to assume the voltage of a motor to be the same for all loads and speeds, and especially so at starting, when from its very nature it takes an abnormally great current. If the efficiency in a test is carried back to the poles of the dynamo, then the voltage at those poles must be taken, in which case the line losses need not be considered separately but will be included in those of the motor. In giving an efficiency, one ought always to state between what two points in a power transformation that efficiency is taken, otherwise it loses much of its value. Moreover, electrical measuring instruments are not always like scales and foot rules, but to be of value when used in tests they should be accompanied either, preferably, by recent or subsequent calibration, or else their style and the name of their maker should be given so that electricians can form some idea of their accuracy and reliability. In general it is advisable for mechanical and civil engineers to at least consult an electrical engineer before they make electric tests for publication if they want such tests to have their highest value.—Electrical World.

Increasing Use of Gas for Cooking.

At the last meeting of the American Gas Light Association, held in Boston, President White in his address made the following reference to the increasing use of fuel gas:

"But, having granted that electricity was a great spur to our side, and that its advance taught our patrons the need to them of a more profuse illumination than that which formerly answered their purpose, in my opinion the main cause of the advance shown in our gas output is to be traced to the pertinacity with which the introduction of gas for purposes other than lighting has been followed. I certainly am not wide of the mark in saying that many, even of our fairly large companies, are to-day, or have been during the summer season, sending out more gas, for purposes other than illuminating, than was sent out by them 15 years ago for every purpose. What is the inevitable knowledge that this brings to us? What is it that this so plainly shows us the future shall be? (1) That our field is to be many times larger than any that we ever dreamed could be our portion—that it is really bounded only by the limits of the habitable portion of the various communities to which we cater; (2) that we are growing closer every day to the 'poor man' as our ally. During the past two seasons, more particularly in the last, the use of gas for cooking purposes has increased phenom-

enally. Thousands of cooking appliances have been placed, and, in fact, in the city of New York, it is rather the rule than the exception now that architects, arranging for the construction of large apartment houses, prepare their plans for the placing of gas cooking ranges instead of coal ranges. New and ingenious schemes or plans for encouraging the domestic use of gas have been thought out and applied. Lectures by experts in the 'art culinary' have been given, with much attention to detail; repeatedly, even in our smaller cities, prizes have been put up for competition among the matrons and maids of several towns, and now comes Cincinnati, where our ex-president, General Hickenlooper, proposes to award \$500 in money prizes for competition by the female pupils in two prominent high-schools of that city.

"Ten years ago such schemes would have been regarded with, to say the least, marked disfavor; to-day they are accepted by us as legitimate and praiseworthy aids to the spread of our industry. This matter of increasing the day sendout will call for primarily but one important expenditure on plant account—the augmenting of holder capacity, and that expenditure will repay us double-fold, in that it will insure such capacity for all needed purposes, either by day or at night, enabling us to work more economically over the entire time in our generating plants. Here, too, it may be said that in this respect an auxiliary water-gas plant will be of advantage. I am not unmindful of the fact that differential rates have played an important part in the spread of the use of gas for purposes other than lighting, nor do I lose sight of the fact that the steady and gradual reduction all around in the prices of gas—a positive evidence that gas engineers are wide awake to the betterment and closer working of the plants in their charge—is going on."

Measurement of Light.

A beam of light has two other qualities besides that of illuminating a dark surface. It can easily be shown to possess more or less heat rays; also, that if certain compound substances are interposed in its path chemical decomposition takes place. Were the three portions of the beam, viz., the thermal, the luminous, and the actinic or the chemical rays always united in the same proportions, we should have no difficulty in constructing a photometer accurate in its measurements and independent of the want of sensitiveness in the eye; for we could on the one hand use a thermometer, or a thermopile and a delicate galvanometer; or on the other hand a piece of sensitized paper such as is used in photography. But unfortunately the proportions vary considerably.

Tyndall has ascertained, as the result of a long series of carefully performed experiments, that the luminous rays from several sources of light bear but a small proportion to the obscure or nonluminous rays, the exact proportion of the former being, from

An oil flame.....	3 per cent.
A gas flame.....	4 " "
A white-hot spiral.....	4.6 " "
An electric arc light.....	10 " "

The arc light appears here as the richest in luminous rays; it is also the richest in actinic rays, but the poorest in thermal rays. The various proportions differ, however, to some extent with different carbons, etc. The experiments demonstrate that, if either the thermal or the actinic rays are to be utilized for ascertaining the luminosity of electric lamps, they can only be compared together, or among themselves; they cannot fairly be compared with an oil or gas flame.—Electrical Age.

The Language of the World.

Some interesting statistics have been compiled by a Frenchman respecting the different languages spoken in various parts of the world. He states that the language in which Shakespeare and Milton wrote was then that of less than six millions of human beings. French was the mother tongue of at least thirty million people at a time when English was spoken by less than sixteen million, and fifty millions of French-speaking people were living when the revolution broke out in 1789. Between 40 and 50 years ago the English language equaled the German in the number of those who spoke it, and now the latter is left far behind.

German is now spoken by 10,000,000 persons in the Austro-Hungarian Empire, by 40,000,000 in the German Empire, by 40,000,000 in Belgium, and by about 2,000,000 in Switzerland. German is also spoken by about 2,000,000 persons in the United States and Canada, giving a total of about 60,000,000 who use the German language. French is spoken by the 38,000,000 inhabitants of

France, by 2,500,000 people in Belgium, by 200,000 in Alsace-Lorraine, by 600,000 in Switzerland, by 1,500,000 in the United States and Canada, by 600,000 in Hayti, and by 1,500,000 in Algiers, India, the West Indies and Africa, in all about 45,000,000. English is spoken by 37,000,000 persons in the British Isles, by probably 57,000,000 of the 60,000,000 inhabitants of the United States, by 4,000,000 persons in Canada, by 3,000,000 in Australia, by 3,700,000 West Indians, and by 1,000,000 in India and other British colonies, bringing the total of the English speaking race to over 100,000,000.

Ethnology of the Eskimos.

A clear and pleasant account of the Eskimos appears in recent numbers of *Das Ausland*, from the pen of Fridhuf Nansen, the celebrated explorer of Greenland.

From their close similarity wherever found, and from the slight differences in their dialects, he believes them to have developed from some small and homogeneous stem in comparatively recent times and to have spread along the coasts of the icy sea. He expresses some doubt as to whether they occupied the southern extremity of Greenland when it was first discovered by the Northmen. The point from which they spread he believes to have been somewhere on the shores of Behring Sea or Behring Straits. In this he differs from Dr. Rink, who places their earliest assignable abode in the interior of Alaska, and still further from Mr. Murdoch, who, with greater probability, would locate it about Hudson Bay.

Nansen's description of the appearance, habits, and arts of the East Coast Eskimos is both amusing and instructive. He found them, in spite of many nasty habits, attractive in character and of good mental ability—all the better, the less they had been subjected to the influence of European instruction and religion. One of their curious superstitions is that they will not touch their hair, in the care of which they take great pride, with any object made of iron, not even to trim it. This recalls similar objections to that metal in the rites of ancient Rome and Egypt. Physically he describes them as a well-made race, quite of the average European height, the young women sometimes good-looking. The general tone of this article is highly favorable to the stock.—Science.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

IOSHUA HENDY MACHINE WORKS, 39 to 51 Fremont St., San Francisco.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

Electricity.

Local Streetcar Line Extensions.

Many changes are to be made during the coming year in the streetcar systems of San Francisco. Old lines will be remodeled with cable or electricity for power, and many new roads will be built. The Western Addition and the southern part of the city will have many new lines and old ones will be extended. The lines and extensions of the Market street system alone will involve the employment of a great amount of labor. Mr. Joseph L. Willcutt, secretary of the company, states that all of the new lines and extensions are to be begun as soon as the routes are graded and prepared for the substructure. On Mission street, near Thirtieth, 50,000 yards of grading has to be done, and as soon as those interested complete this work the Mission road will be extended to the county line and to other and adjacent districts.

A beginning of the proposed improvements and extensions has been made on Kentucky street, from King street to the carhouses at the Potrero. A double track is being laid with heavy rails, and will be completed to the carhouse within two weeks. The old tracks will then be torn up and the street where they are now laid improved. The line will ultimately be extended west to Fifteenth avenue, South San Francisco, just as soon as the roadway is in proper condition to lay the tracks.

For the present the Kentucky street line will continue to use horses as the motive power, but at an early day this system will be discarded and electricity, either by the trolley or storage methods, will be substituted. For three weeks past about 500 men have been employed on this line. Subsequently the company promises to extend the line to Market street, via Fifth. The total length of this branch is three and half miles.

The next work to be done will be the changing of the Mission-street from horse to electric-power, and the only thing that is delaying the work is the delay in the grading at Thirtieth street. The road will be entirely a new one. All of the present rolling-stock of the present line is to be discarded and new bought. It is to be extended to the county-line and to have several lateral branches, and will make transfers wherever its line crosses the tracks of the same system. A branch is to start from Cortland avenue and run to Butler street through California and Richland avenues to a junction with Mission, thus accommodating the residents of the Holly Park district. The length of the Mission-street line and its branches will slightly exceed ten miles. The plans insure the completion inside of six months.

From Thirtieth street the Church and Fillmore street cable line to North Beach will run. Work will be begun as soon as material arrives, and the whole road is to be built just as substantially as the Geary-street. The rails are to weigh 71 pounds per yard and the length of the line will be 4½ miles.

To be built with the Mission is a branch to be driven with electricity, which will connect at Mission and Twenty-ninth streets and run to Noe, a distance of half a mile.

At the corner of Mission and Potter streets will be the terminus of a new cable system to be built on the same substantial plan as the rest and on the same general plan. This branch will run along Potter to Market street, across Page street, thence to Masonic avenue and Frederick street, where it runs west to Golden Gate avenue and terminates at Golden Gate Park. Length, two and a half miles. This line will be driven from the cable-house at the corner of Valencia and Market streets.

Starting at Seventeenth and Castro streets, a new cable branch will be run across to Devisadero street, to Lombard, thus making the second crosstown line connected with the Market-street system and making four altogether, exclusive of the one projected by Senator Fair. The Devisadero branch will be two and a half miles long.

Connecting at Kentucky and Solano streets an electric line is to run along the latter thoroughfare to Santa Clara street, thence up Sixteenth and Seventeenth streets to Carl and Frederick streets to First avenue and the park. Part of this branch will be run as a cable line. At Solano street this branch connects with a line to Market street up Sixth or Seventh streets and at Potrero avenue.

Another connection will be made with a line extending south to Twenty-second street, thence to Chattanooga, to Twenty-fourth, to Hoffman avenue; total length of this line and branches, eight and three-quarter miles.

Another cable line will intersect at Fill-

more and Turk streets, to run along Turk to First avenue and D street and thence to the park; length, two and a half miles.

The total of the new lines which the directory of the company says will be in operation by a year from this date is thirty-four miles, and at a low estimate means an expenditure of over \$3,000,000.

The company, Mr. Willcutt stated, is studying with great minuteness the development of electricity as a mode of propulsion for streetcars, but no electrical system so practical as the trolley has yet demonstrated its ability to fulfill the necessary requirements. It is hoped that some new storage-battery system will be devised so that an experiment as to its merits may be made on the Kentucky-street branch, and the company is prepared to adopt any plan the promoters of which may prove its practicability. For the present a trolley system will be used.

Where The Block System Fails.

THE tremendous volume of passenger traffic on our thousands of miles of steam railroads every day in the year makes the subject of proper protection of running trains from danger of collision with other trains on the same track a matter of the greatest importance. As is well known, the best protection yet afforded in this respect is that furnished by the block signal system, in which the road is subdivided into sections of such a length that it is impossible to give up an entire section to a single train so long as that train is passing through it. It is well known by those who have given any attention to the subject, that the very best block system becomes absolutely worthless if the signals which are automatically displayed are not implicitly obeyed by engine drivers. Experience has shown that a very large percentage of engineers are ready to take large risks even when the signals indicate that there is danger in running past them. A case in point is the rear end collision on the Central Railroad of New Jersey at Greenville, N. J., a few days ago. In this case two trains were dispatched from the station in Jersey one minute apart. Both trains were running at a high rate of speed, and both were behind time, owing to a somewhat dense fog prevailing at the time. The train in the lead, owing to the supposed accident, came to a standstill just beyond the signal post which marked the entrance to one of the 2000 feet blocks into which the entire road is divided, and which are protected by the Westinghouse electro-pneumatic signals. The distance or caution signal was 2000 feet back, that is, upon the same post with the home signal at the entrance to the preceding block. The following train came along at a high rate of speed and could not stop until a rear end collision with the preceding train had taken place. In this case the caution signal told the engineer of the following train that the train ahead of him was in the next block, and he understood well enough that his speed ought to be decreased, so that he would be able to stop before entering the block, 2000 feet ahead of the caution signal. As it was, he disregarded the caution, and being behind time, took the risk, expecting to find the block clear, and continued at the ordinary speed, even though the dense fog prevented him from seeing the train ahead until he was almost upon it. The point of all this is that the block system as at present operated gives ample protection only when the signals which it displays are strictly obeyed. Just here an important advantage would be gained by the substitution of electric power for steam in the operation of trains at high rates of speed, for in this case the automatic signal system could compel the engine driver to obey the signal by cutting off the current from his train as soon as he had passed the distant cautionary signal. Under these conditions, providing the blocks were of sufficient length, it would be impossible for a rear end collision to occur, as a system of automatic switches might be arranged so that a dead section of the line would intervene between any two moving trains. An effort has been made to secure the same results in steam railroad operation by equipping the locomotive with an apparatus by which upon passing a cautionary danger signal the throttle is automatically closed by the action of a solenoid through which the circuit is closed as the signal is passed. In this case, however, each locomotive must be equipped with the apparatus, while in the case mentioned above the equipment would be entirely out of the engineer's control and would be a part of the line equipment rather than an accessory to the electric locomotive.—Electrical World.

A MAGNESIUM FLASHLIGHT for light-houses is being tested for the U. S. Light-

House Board by Maj. D. P. Heap, in charge of the Staten Island station. The apparatus is devised by Prof. C. C. Schirm, of Berlin, and without the assistance of lenses or prisms, it is rated as equivalent to from 200,000 to 300,000 candle power. The apparatus consists essentially of a benzine-tank through which atmospheric air is drawn by a bellows and charged with gas; a vessel containing magnesium powder and pumicestone; clockwork for operating it, and a two-burner benzine lamp. A certain quantity of the magnesium powder falls at regular intervals, is taken up by the jet of gas-loaded air and is ejected from a wide tube and there ignited by passing over the flames of the lamp. The sudden flash thus produced has red rays in it, and can be seen for more than 8 miles on a clear night.

Car Lighting and Heating.

A comparative estimate, made by an English engineer, as to the cost of train lighting by gas, oil and electricity, says the *Electrical Engineer*, indicates that oil varies from one to two cents per lamp per hour, while the cost of plant was about five per cent less for electricity than for gas. This will be a welcome piece of news to railroad companies. The superiority of the electric light in giving more uniform illumination and not fouling the air commends it, irrespective of any question of expense. For heating, also, it will prove a competitor. When we consider the heat wasted in the chimney of stoves—the most common type of car heater—the lack of economy in electric heating assumes a less serious aspect than appears at first glance. A large saving is effected in developing the whole duty of the train from one furnace, and the electric heater expends all of its energy on the air to be heated, instead of imparting a small percentage to a metallic surface and sending the balance outside a car where it figures purely as waste. With steam heating the comparison would not be so favorable in cost, but convenience and safety would be strong factors in favor of electricity.

ELECTRIC STREET-INDICATOR.—A street-indicator for electric cars has been tried recently by the Albany Ry. Co., of Albany, N. Y., says the *Engineering News*. A similar method of announcing the names of cross streets, used for a time on the South Chicago cable roads, was worked by the gripman, and it was found to be more than the gripman could attend to. The Albany indicator is placed inside the car over the door, and consists of a series of narrow signs so arranged that only one is visible at a time. The indicator is operated automatically by a current from the trolley wire. A finger projects down from the trolley support wire near each street corner in such a way as to strike a trigger on the trolley-arm of the car. The effect of this is to turn the indicator one notch, so as to display the name of the street which the car is approaching, and ring a bell to attract the attention of the passengers. As these fingers are at some distance from the street corners, passengers are warned in time to notify the conductor where they want to stop. It is said to be a decided improvement on the oral method of announcing the names of streets, as there is no danger of misunderstanding the name, and it eliminates the frequent opening of the car door in cold weather. As soon as the car reaches the end of the line, the reversing of the trolley changes the mechanism of the indicator, and the signs are reeled off in reverse order.

STINTING BOILER CAPACITY.—It is poor engineering to stint a plant in its boiler capacity. Just as soon as the boilers are forced beyond the capacity of their heating surface to absorb the heat generated in the furnaces, their efficiency is impaired, and although more steam is furnished, less water is evaporated per pound of coal burned. On the other hand, says *Power*, so many boilers or so large a boiler should not be used that a brisk, rapid fire cannot be maintained, the greatest efficiency appearing in the boiler, as in the engine, when there is the greatest difference between its initial and final temperatures. High furnace and low uptake temperatures are essential to the best economy in the boiler-room. The ideal equipment will always comprise a spare boiler, so that not only extraordinary demands for steam may be met without forcing, but the engineer may have an opportunity (without regard to Sundays and holidays, and without interfering with the regularity of their operation) to keep the boilers in a safe and efficient condition, which means the difference between six or less and two or more pounds of water evaporated per pound of coal burned.—Manufacturers' Gazette.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THE CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable.

PRICE, \$675. f. o. b.

Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge.

THE SAN JACINTO ESTATE—Office of the General Manager. CAJALCO, Oct. 30, 1891.

GEO. E. WOODBURY, Esq.—Dear Sir: In reply to yours of the 27th inst., respecting the working and efficiency of the "Woodbury" Concentrator placed in our works by you, I am pleased to inform you that it is giving entire satisfaction; it has a much greater capacity than any other machine, and is doing fully one-third more work, with the concentrates equally clean, as from either of the machines at work here.

(Copy) Yours faithfully, S. HARRIS, Manager. THE SAN JACINTO ESTATE, LIMITED—Office of General Representative, P. O. address, South Riverside, San Bernardino County.

CAJALCO, February 17th, 1892. GEO. E. WOODBURY:—Your letter of inquiry about your concentrator came to hand in due course. Your machine is doing well, the motion is all right, and the machine is giving entire satisfaction. Yours faithfully S. HARRIS.

PATENTED Aug. 19, 1890.

GEO. E. WOODBURY, Man'r, 213 to 219 First St., San Francisco

FULTON IRON WORKS,

HINOKLEY, SPIERS & HAYES, Proprietors.

(ESTABLISHED IN 1866.)

Office, 218 Fremont St.,

DEWEY & CO.'S

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

NEW HOIST.—*Amador Ledger*, Dec. 29: We stated last week that the new managers of the Hardenberg mine had made a contract with Knight & Company for the repairing of the machinery in that mine. That was the determination at the time, but subsequently they have decided to put in an entirely new hoist, and Knight & Co. are at work upon that, expecting to have it completed in about ten days. H. E. Tripp, of the Tripp mine, near the Mokelumne bridge, is sinking another hundred feet in his mine. Supt. Tibbitts of the Albany and Belmont mines states that they had the water under control at the Belmont until the recent storm commenced, but that it was gaining once more. The Coyote gravel mine near Oleta, one day last week, took out a carload of gravel which produced \$3.70 and another which produced \$9.40, while the average is \$2 per car. D. O. Hughes of Sutter Creek, the superintendent, will go to San Francisco next week to make a sale of the property, or else make arrangements to put up a mill. The title of the Bunker Hill mine, which was sold by the sheriff six months ago and bid in by the workmen who had attached for \$11,000, had to be redeemed or pass into their hands on Wednesday last. On Tuesday evening, S. N. Knight telegraphed from San Francisco asking that the transfer be delayed for a few days. Frank Lan-hion circulated a petition among the claimants asking that the delay be granted. However, the deed was secured by John Mitchell, who represented the workmen. W. J. McGee will make the Bunker Hill employee a present in the form of \$73.863, being 50 per cent of the amount due them as wages for labor in the mine. B. F. Fisher has arranged with John Mitchell, representing the men, for the redemption of the property.

Fresno.

THE OLD DISTRICTS.—*Fresno Republican*, Dec. 29: The principal gold-mining districts in this county lie north of the San Joaquin river, and are known as the Potter Ridge, Fine Old and Quartz Mountain mining districts. The metalliferous belt trends northwest and southeast. The mines now being profitably worked in these districts are the Gambetta and Crystal Spring mines at Grub Gulch, the Swanstrom mine and McClelland and Melvin mine at Coarse Gold, the Waterloo and Last Chance mines at Fine Old, and the Lillie and Zebra mines near Quartz Mountain; all of the above-named mines are valuable properties and their records as gold-producers are assured. South of the San Joaquin river some quartz-mining has been done, with a fair degree of success. There are a number of properties there that could be made to pay handsome returns on investments, if they were placed under thoroughly practical management. Some years ago copper-mining was one of the leading industries of this county, and could now be revived and placed on a paying basis. The same mineralized zone or cupriferous belt on which is located the Union copper mine at Copperopolis, Calaveras county, traverses nearly the whole length of this county, having a trend nearly north and south, and dips to the east at an angle of 70 degrees from horizontal. The ores found in this belt are an oxide and carbonate of copper, which changes to a sulphide ore below water-level. Large quantities of copper ores have been mined from the Buchanan, Green Mountain and Ne Plus Ultra mines and shipped to England for reduction, but with our improved modern methods of treating this class of ores, many thousands tons could be extracted from the above-named mines and reduced to a profit at the mines. The Knepper copper mine, situated 27 miles east from Fresno City, is on the same belt. Although but a limited amount of developments have been made on it, it is a most encouraging prospect and worthy the attention of capital seeking investments in that class of mines. Only a limited amount of developments have been made the past season in the silver and iron districts of the county. "Representative work" was done at Mt. Raymond, on the silver and iron districts there; also at the Mineretts mining district, which has been thoroughly examined the past year by competent mining engineers in the interest of an English syndicate. What may be done in those districts in the future it is difficult to say; but it is quite certain that the construction of a railroad to these districts is one of the most essential features toward the successful development of those mountainous districts. The extension of the Pollasky or Raymond branch of the Southern Pacific to those districts would not only benefit them to a great extent, but would place the whole mining business of the county on a more healthy and substantial basis.

Lassen.

HAYDEN HILL.—*Bieber Tribune*, Dec. 29: Dan McLane, Superintendent of the Hayden Hill Tunneling Co., and Dan Ambrose, a shareholder in said company, report that the tunnel (which is seven feet in height and eight feet in width) is in about 600 feet, and that the prospects are very encouraging. This is an enterprise that should be encouraged by every citizen of this community.

Mono.

A MINING CONTRACT.—*Chronicle-Union*, Dec. 29: Sheriff Cody has let a contract to Harry Trevaathan to sink a combination shaft on the Rattlesnake and South Extension to a depth of 200 feet and a 15-foot sump. It will be a double-compartment shaft, and to be finished in eight months. This is a promising mine, several thousand dollars having been taken

out while merely doing assessment work. Sheriff Cody will have a better position superintending his Rattlesnake than being tax collector at \$300 a year.

Nevada.

Mt. GEORGE MINE.—*Telegraph*, Dec. 30: Very flattering reports come from the Mt. George mine. There is a three-foot ledge in it now and gold is seen all through it. The mine is on Rush creek, not very far from Nevada City, and is owned mostly by Grass Valley people.

OSBORN HILL MINE.—The above named mine has been bonded by parties in Grass Valley and in a short time active operations will begin on the property. The Osborn Hill is considered, by mining men who are familiar with the property, as one of the best mining prospects in this part of the country. It is admirably located, and in the early days considerable work was done on the mine. Considerable money has been taken from the mine, and a large ledge is there. Active work on the claim will soon begin and it will make times lively around Union Hill.

GRAVEL CHANNEL.—*Transcript*, Dec. 30: It is generally believed that the company who are now running a tunnel in the Hughes ranch, on the old Grass Valley road, will strike very rich gravel when they get the tunnel in. The last pan of dirt taken out of the shaft on the hill before the old company had to abandon it on account of the immense flow of water, prospected very big. The old company, not having the wherewith to put up heavy machinery, went to work running a drain tunnel. Being financially unable to proceed with the work, they bonded the property to experienced Grass Valley miners, and now the work is going ahead and there seems to be no doubt that a big property will be opened up there. The channel runs through the adjoining ranch, known as the Morgan ranch, now owned by the Nevada County Land and Improvement Association, and the new company has bonded the mining interest of the ranch from the association.

Plumas.

GRANITE BASIN MINES.—*Plumas National Bulletin*, Dec. 26: Granite Basin is a country which seems destined to come to the front as a mining camp. During last summer it attracted considerable attention, and the indications are that a greater degree of interest will be manifested next season. From Jo Peppin, who came up to Quincy Saturday, we gathered the following interesting mining items: Our readers have already been made acquainted with the rich developments recently made in the See & Jolly quartz mine, situated in Granite Basin. The owners have quit work for the winter, but will resume early in the spring. They now have a chimney with backs 30 feet deep. Into this they have drifted only 6 or 7 feet. The ore is extremely rich. About 75 tons of ore are in the small mill. The Black Prince, owned by Arthur Christie, is situated a half-mile from the mine above mentioned. Two men are now at work running a tunnel, which is in 450 feet toward the old Mexican chimney. Mr. Christie has just reached the ledge, which is two feet wide, "backs" 150 feet. As there is no mill on the property, Mr. Christie hauled the ore from this mine to the Morning Star mill, over a mile distant. The ore recently developed is estimated at \$20 per ton. Owing to the cold weather, Mr. Waldron is not able to run his mill on the Homestake property. The vein in this mine is about 20 inches wide, and the ore probably worth \$50 per ton. The mine has a good showing. During the past two years, Mr. Bowles has been running a tunnel in his mine, and has just reached the ledge. There is no mill on the property. The Colwell, owned by Sparks & Parker of Oroville, was patented about 16 years ago, and little development work was done until lately. The owners will devote attention to the property next season. The "Oliver Quirk" is a property owned and worked by Jo Peppin. Jo will sink a shaft next summer. The ore worked by him has yielded an average of \$15 per ton. Equally as good ore is below. Adjoining this, Mr. Peppin owns the Allen Chief & Christie locations. He has started tunnels to prospect them. The vein is only ten inches wide, but the ore from it crumbed as a prospect yielded \$50 per ton. The Granite is a quartz mine owned by a San Francisco company, of whose business at the Basin Mr. Jack Hall has charge. The owners expect to operate this mine next summer. The same parties also own two quartz locations at Cold Water. The Morning Star and Trenton are owned by Monroe and others of San Francisco. During the past season they built a lot of tramways, a house, and put in a large gasoline engine for hoisting purposes. Five men are now at work sinking on the ore vein, which is from two to three feet wide. It is proposed to sink the shaft 100 feet during the present winter. A 20-stamp mill, run by water, is on the property. The ore yields from \$8 to \$9 per ton, and the sulphurets nearly \$1000 per ton. Near the Morning Star, W. C. Grave owns two locations. A tunnel 300 feet long taps a foot ledge of \$10 ore. There is a five-stamp mill on the property. Mr. Early, of Oroville, owns a location into which he has driven a tunnel. He also put in arrastres, but has worked no ore yet. Of the Commercial, Jo Peppin has worked out one level, from which he extracted over \$5000, the ore paying him 25 per ton. He will run a 400-foot tunnel to tap the vein 60 feet deeper. From the level worked out, Jo sank a shaft, the vein increasing in width from 10 inches to four feet. He says he keeps this mine to take money out of when he needs it. The Harrison is at Coquet, nearly three miles from Granite Basin. It is owned by San Francisco parties. One level has been worked out, and a 1200-foot tunnel started to tap the ledge 200 feet deeper.

San Diego.

A STRIKE.—*Perris New Era*, Dec. 29: A strike of considerable magnitude is reported

in the Virginia mine, six miles west of Perris. The ledge has been uncovered to the width of the main shaft, and ore assays nearly \$100 per ton. Jerry Shay, the owner of the property, has recently bonded it, and it is believed that within the next few days the new purchasers will take hold of the mine. It is a good property and bids fair to become a leading bullion-producer.

Santa Barbara.

BITUMEN.—*Santa Barbara Press*, Dec. 31: John A. Puffinburg, the expert prospector in oils and mineral substances, returned to this city Friday last, after an absence of ten days at the newly discovered bituminous rock lode, near Punta Gorda station. Mr. Puffinburg had a force of half a dozen men assisting him in uncovering the deposit, which he discovered some six weeks since. He is very enthusiastic about the mine, claiming that it contains a practically unlimited supply of an exceedingly rich quality of bituminous rock. The mine is so located that it will be an easy matter to extract the ore, it being at the base of a gently sloping side-hill, with a deep canyon below, into which the clay and shale "strippings" can be conveniently thrown. The El Rincon Bituminous Rock Company, composed of J. A. Puffinburg, L. J. Girvin and M. M. Salmon, has been organized to prosecute the extraction of the ore, they having secured a lease of a ten-acre tract of El Rincon rancho, the property of Dr. C. B. Bates and Benigno Gutierrez, for a period of ten years. Work will be commenced shortly, and will be continued diligently, as the above named gentlemen are confident that they know a good thing when they see it, and that the El Rincon mine is one of those good things. This is but one of several valuable deposits of bituminous rock which have been discovered in this county within the past few years, and already the mining and handling of that ore has become a respectable industry, besides being a source of considerable revenue to the railroad company. The excellence of bitumen for street and sidewalk paving purposes is becoming more generally known, and, as the richest rock has been discovered in Santa Barbara county, the mining of the same will doubtless in the near future be an important adjunct to the already numerous resources of the county.

Shasta.

NOTES.—*Shasta Democrat*, Dec. 29: The late storm compelled Col. Lyons to temporarily cease work on the new tunnel he is driving on his mine on Rich gulch. Murray and Hull had to temporarily quit work on the Bunker Hill mine on account of bad weather. They have fine prospects in sight. Howkitt & Anderson, who purchased Vandever & Bullard's mine on Flat creek, have got their Huntington mill running in good shape. Another rich body of ore was struck in the Texas Consolidated last week in a winze in tunnel four. A foot wide of the ore will mill several hundred dollars to the ton. The gulches between here and Shasta and Buckeye district are alive with placer miners who are just now making good pay with rockers and sluice-boxes. The early rainstorm was a boon to the placer miners. J. Holman owns six placer claims on Flat creek, and is at work running a 1500-foot bedrock flume to work the ground through. This will enable him to work some rich ground that was skimmed over by former owners. The old Reid mine, under the superintendency of Col. Stephenson, is developing big. A very rich chute of ore was encountered last week in new ground penetrated by a shaft. This mine will be another producer in Old Diggins next year. The Clipper mine on Squaw creek is in the hands of creditors who consolidated their accounts and attached the property. We are informed that the creditors are running the mine and mill to get out their money, which aggregates about \$5500. Simonds and Spencer have bonded their fine prospect on Churn creek, near Churntown, to a San Francisco capitalist named Campbell, who pays down a handsome first installment and agrees to pay the balance in quarterly installments. Mr. Campbell will proceed to develop this fine prospect as rapidly as possible.

TUNNEL.—*Shasta Courier*, Dec. 31: Thomas Mitchell, who was in town this week, informs us that he and his brother Luke are running a tunnel for the Chicago Co., who own the Minnetota or old Levy mine on Spring creek. They are in 60 feet, on a 4-foot ledge of pay ore. The rock shows the "ore," and is getting richer as they push the tunnel. Hockett and Anderson, who purchased the Vandever and Bullard property on Flat creek, started up their Huntington mill a few days ago. The mill will use up ten tons of ore daily. The Calmet Co. is running a 200-foot tunnel on a promising location on Flat creek. J. E. Bell has suspended work at the Round mountain mining property. There has been plenty of water for placer miners the past few days, and they are making the most of it. Murray and Hull have been compelled to cease operations at Bunker Hill. The indications are that they will strike it in olden days did. Parker is pushing work on the mine he bonded on Muletown mountain, and has encountered some rock that assays very high.

Tuolumne.

QUARTZ INTERESTS.—*Union Democrat*, Dec. 31: Our quartz-mining interests seem to be looking up again. Outside capital is taking a hand in the development of some of our mining properties, and we confidently predict a mining boom shortly. We have within our limits gold-bearing veins without number, many of them exceedingly rich in the estimation of experienced miners, and under proper and economical management they can be made to yield rich results. In the past it has been the rule with companies to carry on their operations without regard to costs and expenses. With a few notable exceptions, not a mine has been opened and devel-

oped in a manner to place it in a paying condition. The lack of funds by our miners has worked against the successful development of some, and the lack of knowledge on the part of superintendents and managers has brought discredit on others. As monuments of extravagance and bad judgment, there are to-day in this county several first-class mills without a vein to feed them. Men rich and valuable mines now lie dormant which can be made to yield princely fortunes. First they must be opened and developed. There are many veins that have been worked to a limited extent, and that are known to be rich, that are now idle simply for the want of means to prosecute work on them. As a fact, nearly all of our quartz veins that were found to be rich when first worked and which were abandoned for a series of years, proved to be very profitable when subsequently opened and developed. This fact is becoming generally known and mining men are realizing that Tuolumne's gold fields are comparatively unworked, and the purchase of several of her mines is now being considered by capitalists, with favorable indications that sales will be made, followed by a vigorous and systematic working of the claims.

COLUMBIA.—*Union-Democrat*, Dec. 31: The old Tuolumne mine is looking good. Supt. Davis showed us some rock which disconcerts anything we have seen in a long time. They have not yet struck the main chute, but expect to within a short time. Expert D. Levy is very jubilant over the promising outlook. The Noonday is still sinking on good ore. Ed. Ogden and George Moran have struck a good prospect on the hill back of Morgan's house, near the head of Waterloo gulch. The Ham & Birney mine, three miles east of Columbia, will start up soon after New Year. The owners have recently put in a Huntington mill of large capacity to crush the 600 tons of ore already on the dump. Supt. McKenna, of Otto Kenig's mine, was in town this week. He says their prospects are very bright for the coming year, as they have the mine in excellent shape to work to great advantage. Smith & Fraser, of the Crystal Palace Cave, are washing out an immense pile of gravel which they drifted out during the dry season.

NEVADA.

Washoe District.

CON. CALIFORNIA AND VIRGINIA.—*Virginia Enterprise*, Dec. 30: On the 1500 level the south drift leading to the stopes has been closed. This drift has a winze connection at the south end of our mine openings with the 1650 level, and is near the point where the fire started on that level. The closing of the south drift was necessary, as the good air coming from the 1500 level, north drift, turned and went down the Con. Va. shaft to the 1650 level, then south to the point of the fire, and upward through the upraise to the 1500 level; thence through the south drift to the Combination shaft, and upward to the surface. The result of the turning of the air current was to give good air to the burning stopes and increase the gas and smoke coming through the south drift to the shaft station on the 1500 level. The closing of the south drift has again turned the air, so that the combination shaft is upcast from the 1650 level to the surface. The 1500 level south drift is a level plane without any grade, and by building a three-foot dam across the drift at its mouth and turning in the water, it flows through the drift and down the upraise to the 1650 level. We feel certain this water will reach the fire and accomplish a great deal of good in a very short time. All our bulkhead work on the C. & C. side of the mine is in perfect order. The gas escaping through the Con. Virginia shaft has not increased, nor has it shown any decrease for the past three days. All ore extraction has been suspended during the week. Have shipped to the Morgan mill during the week from our ore bins 310 1270-2000 tons of ore, the average assay value of which, per car samples, was \$28.11 per ton. The average assay value, per battery samples, of all the ore worked at that mill during the week (816 tons) was \$29.15 per ton; 505 730-2000 tons of the ore worked was on hand at the mill, and, being of better quality than the ore shipped from the mine during the week, will account for the value of the battery samples being in excess of the car samples. Bullion shipped to Carson Mint, assay value, \$13,134.73. Bullion on hand in our assay office, assay value about \$30,500.

OPHIA.—1465 level.—The upraise started on the sill floor, on the north side of the crosscut run east from the drift run south from the Mexican sill floor to the Ophir ground, 101 feet below the sill floor of this level, has been carried up 7 feet; total height, 45 feet, continuing in porphyry showing lines of quartz.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 18 feet; total length, 413 feet; continuing in a porphyry formation with lines of quartz.

UNION CON.—900 level.—The joint Union Con. and Sierra Nevada west drift has been extended during the week 20 feet; total length west from the joint shaft, 2748 feet. The face is in porphyry and small streaks of clay, from which there is a flow of about five inches of hot water.

UTAH.—340 level.—West crosscut No. 3 from the north drift from west crosscut No. 2, at a point 195 feet in from its mouth has been extended 14 feet; total length 37 feet. The face of this crosscut is in a porphyry, clay and quartzite formation, showing some water.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 27 feet; total length 481 feet; face in hard porphyry. The joint Sierra Nevada and Union west drift, 900 level,

was advanced 20 feet; total distance west of shaft 2748 feet; face in porphyry and small streaks of clay, from which there is a flow of about five inches of water.

CHOLLAS.—Are repairing north drift on the 450 level, and retimbering main shaft between the 850 and 930 levels. Repairing to east crosscut, 160 feet south of north line, 930 level, is completed, and work resumed in the face of north drift from the crosscut.

POTOSI.—The raise from No. 1 crosscut, 1100 level is up 106 feet; the last seven or eight feet in porphyry, roof showing bunches of quartz. The east drift from Potosi winze station, 1000 level, is out 110 feet; face in porphyry. Extracted and sent to the mill the past week 370 tons 250 pounds of ore from the 550, 930 and 1150 levels. Milled during the week 370 tons; on hand at mill, 71 tons 150 pounds. Average battery assays, \$26.47. Average car sample assays, \$33.31.

BULLION.—West crosscut, 160 feet north of top of upraise, 320 feet south of north line, 1300 level, is out 48 feet; face in soft porphyry. West crosscut from the northwest drift, 300 feet south of north line from Ward shaft, 1800 level, is out 115 feet; face in soft porphyry.

WARD SHAFT.—Joint Alpha and Exchequer east crosscut, on the north line of Alpha is out 155 feet; face in porphyry. The west crosscut, 300 feet south of north line of Bullion from Ward shaft, 1800 level, is out 115 feet; face in clay and porphyry.

ALPHA.—The joint Alpha and Exchequer east crosscut, on north line of Alpha, 1800 level of the Ward shaft, is out 155 feet; face in porphyry.

EXCHEQUER.—The joint Alpha and Exchequer east crosscut on north line of Alpha, 1800 level of the Ward shaft, is out 155 feet; face in porphyry.

SILVEA HILL.—The north drift on the 160 level has been advanced nine feet the past week; face in hard porphyry and small stringers of quartz, the car samples from which average about \$3 in gold. The southeast drift, 450 level is out eight feet; face in hard porphyry.

NEW YORK.—The south drift from the winze, 700 level is out 36 feet; the face shows 24 feet of ore, car samples averaging \$35. The west crosscut, 55 feet north of the shaft, 850 level, is out 56 feet; face in quartz yielding low assays. Are extracting from the stope above the 650 level 10 cars of ore per day, car samples averaging \$30. Shipped to the Washoe mill the past week 163 tons 1190 pounds of ore; on hand at mill, 60 tons; average battery assays, \$36.27; average car sample assays, \$37.60. Shipped to the Carson Mint 276 pounds of crude bullion.

HALE & NORCROSS.—We continue retimbering main shaft above the 700 level. Main Incline—Are making the necessary repairs, and are retimbering incline above the 1800 level, 1800 level. Advanced No. 1 west crosscut 16 feet; total length, 255 feet. The face at this distance reached the west wall and work was discontinued in this crosscut. West crosscut No. 3 was advanced 17 feet; total length, 192 feet; face in porphyry, showing some quartz. Advanced No. 4 west crosscut 16 feet; total length, 44 feet; face in quartz.

ANNES.—On the 420 level no work has been done in face of north drift run from east crosscut No. 1, north, during the week. Work has been confined to retimbering and repairing main north drift.

BEST & BELCHER.—200 level—During the past week the northwest drift has been advanced 22 feet through soft porphyry and quartz; total length, 108 feet. 300 level—West crosscut No. 2 has been extended a total distance of 105 feet and discontinued; face in porphyry. Started west crosscut No. 3 from top of upraise No. 1, which was carried up from the 1000 level, and advanced same 12 feet; face in porphyry.

GOULD & CURRY.—200 level: West crosscut No. 5, 435 feet from main west drift, has been advanced 20 feet through porphyry and stringers of quartz; total length 197 feet. West crosscut No. 6 from main north drift has been extended 9 feet; total length, 45 feet; face in quartz. On the Sntro tunnel level, the joint north drift with Savage Co. has been advanced 15 feet during the past week; total length, 759 feet; face in very hard porphyry.

EAST BEST & BELCHER AND NORTH GOULD & CURRY.—Are drifting from East Best & Belcher toward North Gould & Curry. Going through porphyry with favorable indications in the face.

OCCIDENTAL.—The upraise from south drift, 750 level, is up 51 feet and continues in ore of fair grade. The main north drift, 750 level, has been extended 17 feet; face in hard quartz giving low assays. Crosscut No. 2 in Zedig drift, Sntro tunnel level, has been advanced 16 feet; total length, 87 feet. The face is in clay and porphyry.

Ferguson District.

HARR KNOCKS.—Pioche Record, Dec. 29: Ferguson district, a few months since our El Dorado, is experiencing some hard knocks. The forfeiture of the April Fool option some time ago and the nonresumption of work there, is followed by a forfeiture of the Magnolia bond and a stoppage of work on that property also, which has always been regarded as the mainstay of the camp. While the Magnolia is admitted generally to be a good prospect, a man is not justified in going wild over it. No particular change has occurred in its appearance for some time past. The last and final payment on the property, of \$42,500, would have been due on the 15th of next month. The main shaft on the claim is down about 140 feet, and to properly prosecute the work deeper would necessitate the erection of a whim or steam hoist. With supplies of all kinds difficult to obtain, this would occupy some time—three weeks at least—and the bondholders asked for 60 days further time in which to prospect

the claim after the erection of the hoist. Some of the locators agreed, while others wanted a bonus of \$10,000 for the privilege. In the opinion of the bondholders, the property did not warrant this, and on Friday last Supt. J. L. Powell, then in charge, stopped all work and turned the mine over to the original locators. With all work stopped on the Reed tunnel, and no active work going on in the April Fool claim, the district is correspondingly dull and quiet, and will probably remain so until new deals can be effected, or new discoveries are made there.

Yellow Pine District.

ORE PRODUCERS.—Pioche Record, Dec. 26: That the interest now centering in the Yellow Pine district, in this county, is not without a good mineral foundation may be forcibly illustrated by a review of the properties there, which at this time are regarded as ore-producers—the claims, in fact, which will be relied on, without further discoveries, to supply the 200 tons of ore a day required by the incoming branch road from Gold. A number of immense lead deposits exist in the district, among the foremost of which comes the Mountain Top group, situated some 24 miles southwest of Good Springs and embracing nine claims. The Mountain Top claim itself has been sunk on for but 15 feet, exposing ore for 10 feet, the ledge or ore body being six feet wide and is a nearly horizontal vein or deposit in limestone. The ore is mostly galena and lead carbonate, with a siliceous gangue running 40 per cent lead and 12 ounces silver per ton. Twenty-five tons of ore lie on the dump. The Mountain Top extension, adjoining, is in the same formation, with a three-foot ledge. Twenty-five feet of ore is exposed on this claim, and the deepest workings are but 50 feet. The ore runs 50 per cent lead and 25 ounces in silver, and 25 tons lie on the dump awaiting shipment. On the Lookout claim more work has been done; the ledge here is the same as in the Mountain Top, and is four feet in width. The deepest workings are 60 feet, while altogether 70 feet of ore is exposed. The grade continues to improve, carrying 35 ounces silver and 40 per cent lead. Two hundred tons lie on the dump. The Copper & Lead, another claim of this group, of the same character of ore as above, has a six-foot vein sunk on to a depth of 75 feet, with 20 feet of ore exposed, which runs 50 per cent lead and 20 ounces silver; 100 tons are extracted here ready for market. The West Side and Ruby silver claims are also of this group; both show ore from one to three feet in width, the ledge being a bed vein, with limestone walls, dipping to the west at an angle of about 15 degrees. The deepest workings are but 10 to 15 feet below the surface, but 50 feet of ore is exposed on the west side and 250 on the Ruby Silver, averaging from 35 to 40 per cent lead and from 20 to 35 ounces in silver per ton. Sixty tons are mined here and await shipment. The Volcanic has a larger vein, but is much broken up and is much poorer. Though it has only been scratched on top, the ore is exposed for 250 feet. The ledge is composed principally of quartz and calc spar. The ore averages 14 per cent lead and 14 ounces in silver. The Galena and Chicago claims, which complete this group, have a similar vein to the West Side and Ruby Silver, running from one to five feet in width. The Galena has a 75-foot shaft, with 50 feet of ore exposed, while the Chicago is not more than uncovered. The ore in both claims is clean galena and lead carbonate, running 70 per cent lead and 40 ounces silver. About 60 tons are extracted. A conservative estimate of the probable output of this group, on the developments already made, is 100 tons of ore a day, and every indication goes to show that it might be continued for an indefinite length of time. The Oklahoma and Full Moon claims, two other good lead properties, are situated about six miles southwest of the springs, and will produce 20 tons of shipping ore a day from the start. The ore is found in a nearly horizontal deposit or vein in limestone, and runs about 40 per cent in lead and 30 ounces silver. Forty tons are ready for shipment from these two claims.

ARIZONA.

PECK MINE.—Cor. Prescott Courier, Dec. 29: The sawmill started at the Crowned King today and will saw 60,000 feet of lumber. The quartzmill will start up in a few days. There is now enough water to run. Work has commenced on the main shaft at the mine, and will sink 500 feet. Very rich ore is being taken out of the Eclipse mine, owned by Luke & Luke of Phoenix. Several tons of \$600 silver rock have been taken out lately. The Del Pasco mill will also be running in full blast in a few days. A big lawsuit has been commenced in the district court which will rival the celebrated Bond-Luke suit. The suit is brought by Mendibles and S. Mott against Ernst Arnaz, the well known young mining man and politician, and B. F. Joslin, to set aside a deed that Arnaz and Joslin hold for one-half of the Western Star mine. The mine is one of the most promising properties in this district. All of the burro pack trains have left this camp on account of the late snow storms, the snow being 18 inches deep on top of the Del Pasco. Several placer miners are now at the Cave creek placer mines, with fair results.

MOHAVE COUNTY NOTES.—Miner, Dec. 30: Frank Hamilton has a couple of tons of ore from the Mississippi mine, Wallapai mountain, awaiting shipment to the Colorado smelters. John Barry sent in a couple of tons of rich concentrates from the Minnesota mine, near Chloride, this week, and will ship them to the Pueblo smelters. Tiborcio Padillo has three men at work on the old Rainbow mine in Cedar and is taking out considerable ore. He has about 100 sacks on the dump and expects to make a shipment next month. There are six men at work on the Pittsburgh mine, Chimehueva mountains. The property, owned

by Monaghan & Murphy, is showing up finely with development and considerable ore is being extracted. Two carloads of concentrates were hauled down from the C. O. D. mill Wednesday by Brown's ore teams and were unloaded on the depot platform preparatory to loading on the cars and shipping to Denver. Messrs. Galigher, Sanfley and Marshal have sold one of their claims to Ed. Phenix, the purchaser paying \$1000 for the claim. This property adjoins the Bonita mine, belonging to the White Hills Company and is a good-looking prospect. Jas. Penberthy came down from the American Flag mine, Wallapai, mountains, yesterday. He informs us that there is now on the dump, sacked up and ready for shipment, nearly a carload of ore. Mr. Penberthy says there is a good body of ore in sight awaiting extraction and that if silver would come up to gold in value he would soon take out ore enough to make him independent for life, but at the present disgraceful condition of silver it is impossible to make a large percentage of the ore pay, owing to the heavy transportation charges. The ore has to all be packed out on burros, over a rough mountain trail, a distance of 15 miles, before it can be reached by ore teams, and taking everything into consideration, the ore must run away up into the hundreds before it can be handled profitably by the owners.

A RICH STRIKE.—Tombstone Epitaph, Dec. 24: The T. M. & M. Co. has been sinking a shaft for a week past on the west end of the Northwest claim near the line that divides that claim from the triangular claim owned by Jas. Young and O. C. Smith. At a depth of eight feet they struck the ore body which is a continuation of the Smith-Young ledge. On Monday they sacked 20 sacks of 400-ounce ore, and the chimney appears to be an immense one. This body of ore also extends onto the Sweet Nut. Jnd Cummings, who is working near by on a claim just across the gulch, has the same ore body. It is, without doubt, one of the largest and richest ore bodies struck in the history of the camp, and has caused some old-time excitement among mining men.

LOWER CALIFORNIA.

TO DEVELOP THE AURORA.—San Diego Union, Dec. 27: It is reported that Messrs. Russell & Rhodes, owners of the Aurora mine at Alamo, have succeeded in organizing a company to develop the mine, and that work will soon be started on a larger scale than ever. Mr. Rhodes' recent visit to England is thought to be in this connection. The Aurora's total output of gold is unknown to any but the owners, but actual shipments since manifesting has been in vogue have been over \$200,000 in gold, and circumstances indicate that a half million would be more nearly the total. The gold was taken from drifts not more than 150 feet in depth, and the mine can hardly be considered more than a prospect. It is understood that arrangements have been made whereby Russell & Rhodes donate the output of the mine for a certain time toward its development, against a stated cash capital of the newly interested parties. This report, if confirmed, will be good news to Alamo, meaning a new lease of life on a large scale, when now only a few chlorides are at work.

UTAH.

THE SAN JUAN PLACERS.—Aspen Times, Dec. 29: A dispatch was received yesterday at the office of the Denver & Rio Grande road, stating that horses and wagons are being rendezvoused at Dolores for the use of trains crossing the country to the mouth of the San Juan. Pack animals are being utilized, and outfits of all kinds are for sale. One enterprising firm is offering passage to the goldfields in wagon at \$20. It is reported that 1000 adventurers are tramping across the mountains and deserts in a scramble to get in before all the good ground is taken up. Tenderfeet passing through the Navajo country are advised to secure an Indian guide and to be prepared to be self-sustaining for a siege of two or three months. The demand for correct maps of the region is unprecedented. Engineer Aulls, who recently braved the rapids of the Colorado, says he found the map issued by Hayden to be accurate in every detail. The map men of the railways are sparing no effort in getting out maps showing the shortest and quickest route to the placer beds. J. F. Wehner, manager of the Henrietta mine in the Henry mountain district, was a caller at the Rio Grande Western headquarters yesterday. Mr. Wehner is on his way to London, Eng., to negotiate for the sale of the mine. He states that he has prospected the entire region where the placers are said to be located. "There is plenty of gold in the eand of the Colorado and San Juan," said he, "but the trouble is the placer beds lie so high above the river bed that they cannot be worked without the aid of machinery costing from \$60,000 to \$100,000 for each plant. The hydraulic system will have to be applied before placers will yield up their treasures." Speaking in detail, Mr. Wehner said that it is possible there are placers along the river where it will pay for the miner to haul water in wagons for washing out the gravel. He cited a plant in operation in the Henry mountains, where the dirt is hauled to the water and there washed out. "With regard to claim-jumping," continued he, "I have no doubt there are a number of claims upon which assessment work has not been done for several years. Those claims are jumpable according to law and will doubtless be gobbled up before spring." In describing the Henry mountain district, which covers an area of 30 miles each way, the visitor said: "The district was discovered by a party of prospectors from Grand Junction about a year and a half ago. A number of mines have been opened and it is believed by many of us that the district will become one of the best in Utah. The ore is free-milling gold ore. Samples have been tested running into thousands of dollars. A fine stamp mill

is now in operation on the Bonita park property. The vein in the Bromide mine averages twenty-two inches in width, while the Rio Grande mine has a 44-foot vein, a shaft 70 feet deep, and a tunnel 115 feet long. Last summer bullion to the amount of \$3151 was taken out of the Bromide." On November 30th a meeting of miners was called, which was attended by 33 men. J. F. Drake was chosen secretary, and the district was formally named the Henry Mountain mining district. The Bromide mine has an elevation of 9000 feet. So far as can be learned in this city, no man who has gone into that enchanted region has yet returned. It was along this particular stream that the cliff dwellers ages ago made their homes. Denver people are certainly leaving the city for the new fields, but the great majority of them are trying to keep their movements from the public. S. H. Brownlee, of Green river, was in the city yesterday purchasing saddles, blankets and tents for a party of friends who expect to leave Green river on Wednesday next for the new fields. To a reporter for the *News* the gentleman said that the Rio Grande Western had made arrangements with the leading outfitters of Green river to send all people from that point over to the San Juan, and for this purpose a big lot of saddle ponies are now being gathered together. From Green river to Dandy crossing there are ranches every 10 or 15 miles, but after crossing the Colorado river the country is nothing but a desert. Some experienced mining men, who refuse to divulge their names, are organizing a little expedition to explore the unknown land. While these people, of course, want gold, that is not all they are after, as instructions are to make a special search for copper and asbestos.

WASHINGTON.

SWANK MINES.—Cor. Ellensburg Capital, Dec. 30: Placer-mining has just shut down for the season, as there is about two feet of snow here and more falling all the time. About the only mining going on at present is underground. A. B. Morrison and Harvey DeZang are sinking on one of their quartz claims on Bonanza gulch. They are down about 40 feet and have a five-foot ledge of free-milling quartz in lime and slate, the assays showing from \$5 to \$35 per ton. J. H. Price of Williams creek is still working, and has on the dump 40 or 50 tons of \$30 rock. Mr. Price has what is going to prove one of the best properties in the camp. J. T. Brien is taking out some very good rock from his new discovery on Williams creek. He will continue to take out quartz all winter, and just as soon as spring opens will run it through an arrastre. This rock has assayed as high as \$4000 per ton, the average being up in the hundreds. Treet, Johnson & York on Mineral Hill are at work on the Golden Phoenix, and when spring opens will have a big lot of rich ore to grind in their arrastre. The Swank Tunnel Co. has a tunnel in on its claims 150 feet, and is going to crosscutting to strike the main ledge. This is the finest piece of work ever done on the Swank. It was done by H. H. Cole and cost the company about \$6 per foot. The company is incorporated with J. H. Wilson as president and J. G. Boyle secretary. Ford, Kanp & Smith last week struck the main ledge on the Buck Horn, on which they have been crosscutting all summer. Their main tunnel is in nearly 200 feet. They have uncovered three veins of free-milling quartz, one of 18 inches, one of 6 feet, and the last and best is 7 feet wide. It is 12 feet from the first to the second and 18 feet from the second to the third. The last is what is called sngar quartz, free-milling, and goes about \$40 per ton. Quite a number of claims have changed hands this fall and winter at prices ranging from \$250 to \$4000. In fact, all properties on the Swank are looking up. One of our citizens holding some Swank bedrock flume stock was offered last week a ten per cent advance on what it cost him. He declined the offer.

Wanted, A Partner

With capital sufficient to develop a gold mine in Shasta county, California. The property is located in the gold belt from which a large amount in gold is being extracted. The mine is showing well so far as work owned, being from 8 to 12 inches in rich ore. The company owns a mill and water rights, with U. S. patent. Plenty of fine timber on the ground. This is an exceptional opportunity for capital. Address, "SHASTA," this office.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

OCCIDENTAL RAFTING CO. Capital stock \$2,000,000. Directors—W. P. Plummer, H. R. Robertson, Fred M. Wilson, James Logan and J. J. McIntyre.

PACIFIC TRADING CO. Directors—U. J. Lyon, Lamartine R. Fnlida, A. P. Lorentzen, Daniel Vincent and William B. Bradbury. Capital stock, \$250,000.

PACIFIC HOME SECURITY CO. Directors—Wm. H. H. Hart, Sumner W. Engbee, Thomas W. Nowlin and Aylett R. Colton. Capital stock, \$10,000.

PACIFIC ASBESTOS CO., Los Angeles. Capital stock, \$25,000. Directors—T. J. Hannon, A. H. Busch, F. T. Griffith, J. D. Hoff and R. F. Vetter.

DIVIDEND NOTICE.

OFFICE OF THE PACIFIC COAST BORAX COMPANY, San Francisco, Dec. 31, 1892. At a meeting of the Board of Directors of the above-named Company, held this day, a Dividend (No. 25) of One Dollar (\$1.00) per share was declared, payable TUESDAY, January 10, 1893, at the office of the company, No. 101 Sansome Street, Room 28. Transfer books will close January 5, 1893, at 3 o'clock, p. m.

ALTON H. CLOUGH, Secretary.

Market Reports.

Financial and Commercial Review.

SAN FRANCISCO, Jan. 5, 1893.

The London Silver Market.

Last August, fine silver fell to 37 1/4 per ounce in the English market, the lowest up to that time during the present century. Subsequently, the value rose to 39 1/4. Again on the 21st of December the quotation fell to 37 1/4, or 1/4 lower than last August, and of course the lowest in over 90 years. This was shortly after the adjournment of the International Monetary Congress at Brussels at the conclusion of long and unsatisfactory deliberations. The price on the 1st of December was 39 1/4 and at the close of the same month 38 1/4. The extremes for fine silver in the London market for the year were as follows:

1892.	Highest.	Lowest.
January.....	43 12-16d	41 12-16d
February.....	41 13 16	41 2 16
March.....	41 10-16	39
April.....	42 2-16	39 4-16
May.....	40 10-16	39 11-16
June.....	41 2-16	40 1-16
July.....	40 1-16	39 1-16
August.....	39 1-16	37 14-16
September.....	38 5-16	38 2-16
October.....	39 14-16	38 2-16
November.....	39 4-16	38 12-16
December.....	39 3-16	37 12-16

The extremes for December, 1891, were 44d to 43 1/4d and for the year 48 1/4d to 43 1/4d. What is in store for this metal this year is hard to tell. The usual monthly purchases of 4,500,000 ounces silver by the Government will be resumed to-morrow.

Prices of Silver in December.

The following shows the daily quotations of bar silver in the London and New York markets during December:

Date.	London.	New York.
1.....	39 3-16d	\$0 85 1/4
2.....	39 1/2	85 1/4
3.....	39	85
4.....	38 3/4	84 3/4
5.....	38 3/4	84
6.....	38 3/4	84 1/2
7.....	38 3/4	84 1/2
8.....	38 3/4	84 1/2
9.....	38 3/4	84 1/2
10.....	38 3/4	84 1/2
11.....	38 3/4	84 1/2
12.....	38 3/4	84 1/2
13.....	38 3/4	84 1/2
14.....	38 3/4	84 1/2
15.....	38 3/4	84 1/2
16.....	38 3/4	84 1/2
17.....	38 3/4	84 1/2
18.....	38 3/4	84 1/2
19.....	38 5-16	84 1/2
20.....	37 15-16	82 1/2
21.....	37 15-16	82 1/2
22.....	38 1-16	82 1/2
23.....	38	82
24.....	38	82
25.....	38	82
26.....	38 1/2	82 1/2
27.....	38 1/2	82 1/2
28.....	38 1/2	82 1/2
29.....	38 5-16	82 1/2
30.....	38 5-16	82 1/2
31.....	38 5-16	82 1/2

The London quotations are per ounce 925 fine and 1000 fine in New York. The highest and lowest prices for the month were as follows:

	London.	New York.
Highest.....	39 3-16	\$0 85 1/4
Lowest.....	37 15-16	82
Difference.....	1 1/4	3 1/4

The closing prices for the month were 3/4d and 2 1/4c lower in London and New York, respectively, than at the opening.

In November the London market opened at 39 1/4d and closed at 39 1/4d. The highest price in that month was 39 1/4d. The New York market opened at 84 1/2c and closed at 85 1/4c, the highest being 85 1/4c.

During the past month private advices reported a sale of silver in the London market at 37 1/4d (21st), which was the lowest ever known in that market. The lowest price, according to the public dispatches, was 37 15-16d, as above given. On the 22d, 23d and 24th of the month the New York market stood at 82c, the lowest price ever recorded there.

Exports of Specie.

During the final week in December, 1892, the exports (exclusive of specie) from the port of New York were \$7,235,354, making for the year \$392,712,818, as against \$388,270,774 in 1891.

QUICKSILVER.—Tuesday the Newburn took 175 flasks of quicksilver to Mexico. There is no change in quotations, and little inquiry.

BORAX.—The market is quiet at quotations.

ANTIMONY.—The last Panama steamer took out a consignment of antimony, making about the only event worth noting during the week. Nothing is doing, the market partaking of the quiet usually experienced in metals at this season.

LEAD.—Local jobbing quotations for lead are \$4.25@4.37 1/2 per hundred for domestic. At this season the inquiry is naturally light and sales slow, and the market now shows no exception to the rule.

TIN.—For Australian local jobbing quotations are 22 1/2 cents per pound.

COPPER.—No transactions in copper are recorded. Local quotations are steady at 13 1/2 cents.

The Mining Share Market.

There is no special activity to note in the stock market, the year having opened rather quietly on Pine Street. News from the Comstock is, however, encouraging. Tuesday's *Virginia Chronicle* said: "The engine at the Con. Virginia was started up this morning and a number of men put to work repairing the water pipe running down the shaft, which was broken in several places near the 1300 level. The shaft being an upcast the effect in the breaks of the water pipe, whereby the water dropped to the levels below, retarded the escape of gas through the shaft. The volume of gas in the mine has decreased perceptibly. Three shifts of four

men each are at work on the 1500 level, and two more men will shortly be added to each shift. Superintendent Lyman expects to be able to open the stopes on the 1500 level before long, when the force of miners will no doubt be materially increased."

On the 3d inst. the connection between the east and west drifts on the 1000 level of the Potosi mine was made. There is now a good circulation of air, and some energetic prospecting work will be done. Drifting south on the 1000 level of the Potosi toward the Bullion will begin at once.

The following companies had cash on hand on the 1st inst., according to the financial statements filed this morning: Alpha \$148,624.62, Best & Belcher \$242,012.02, Bodie \$57,042, Bulwer \$7894.10, Bullion \$8199.74, Caledonia \$1674.39, Chollar \$522.12, Coptic \$3800, Crocker \$865.95, East Sierra Nevada \$7 to Gold & Curry \$13,978.97, Julia \$3803.10, Kinnick \$2062.99, Lady Washington \$5227.30, Mexican \$14,328.10, North Commonwealth \$2058.10, Nevada Queen \$97.58, Occidental \$9572.57, Peer \$381.62, Peerless \$1784.88, Syndicate \$1280.31, Savage \$2702.72, Scorpion \$3378.81, Silver Hill \$3858.41, Sierra Nevada \$13,558.44, Silver King \$2701.32, Standard Con. \$37,293.59, Union \$7052.84.

The following companies were in debt: Belle Isle \$2217.57, Belcher \$20,154.32, Commonwealth \$26,824.49, Challenger \$9522.20, Con. Imperial \$3372, Crown Point \$14,793.16, Confidence \$12,122.75, Con. Cal-Virginia \$4,296.66, with \$40,081.35 in bullion unsold; Con. New York \$7617.40, Del Monte \$21,612.83, Exchequer \$2500, Hale & Norcross \$8886.69, Independence \$256.66, Navajo \$2525.34, North Belle Isle \$7223.68, Ophir \$4562.71, Overman \$12,365.24, Potosi \$56,099.01, Seg. Belcher \$6975.98, Utah \$14,443.82.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING DEC. 27, 1892.

488,922.—CAR COUPLING—Galloway & Cramer, Plainville, Or.

488,734.—CABLE TRAMWAY—J. L. Giroux, Jerome, A. T.

488,891.—HYDRAULIC ELEVATOR—C. I. Hall, S. F.

488,737.—SAFETY LOCK FOR GAS COCK—F. Lawrence, S. F.

488,971.—LAMP SUPPORT—D. F. Oliver, Oakland, Cal.

488,718.—CAR COUPLING—F. M. Ryan, S. F.

488,721.—BATTER CAKE MIXER, ETC.—F. Stempel, Alameda, Cal.

488,743.—BILLIARD TABLE—Scott & Wright, S. F.

488,723.—WATER WHEEL—Clark Taber, Sumpster, Or.

488,640.—CABLE—J. H. L. Tuck, Stockton, Cal.

488,746.—STEERING GEAR—H. L. Weitzel, Oakland, Cal.

The following brief list by telegraph, for Dec. 27, will appear more complete on receipt of mail advices:

California.—Nelson Evans and W. A. Henry, Ukiah, wagon jack; Thomas E. Fry, Nipoma, animal trap; Milton O. Godding, Monrovia, combined automatic thrasher, feeder and separator; John P. Lighthady, San Francisco, balanced slide valve (2); Antonin Sperl, Los Angeles, and J. Geemen, Cucamonga, portable fruit evaporator; Benjamin H. Stephens, Mendocino, device for raising loaded trucks; F. A. Westheimer, San Francisco, hoisting iron or tongs; Richard F. Wilson, Stockton, non-shrinking stove; Washington—Louise Austin, Whetcom, pinking shears; S. M. R. Gilbert, Seattle, gravel washer, etc.; Chas. P. Labro, Spokane, conduit for electric railroads.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail for telegraphic order. American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CALICO, Dec. 18, 1891.

MESSES. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

The Late Egbert Judson.

Egbert Judson, who died this week, was distinguished among the millionaires of this city as being an original investor in manufacturing enterprises instead of a cent-per-cent man. And not only did he invest his money in industrial enterprises, but he originated and established them, afterward taking an active personal interest in the conduct of their affairs. It has been unfortunate for the city and State that there were not more rich men like him in this respect.

He seemed to possess a remarkable faculty for organizing and building up manufacturing establishments, and his means has been such that wherever he has given his attention, it has brought the confidence of others who have been willing to put in their capital. He not only possessed great executive ability, but was always willing and able to take off his coat, go to work, and show how a thing should be done. There was nothing of the "kid-glove expert" about Mr. Judson, who was a plain man, but one with a great deal of practical experience and plain good sense. All who have been associated with him speak highly of his integrity, industry and ability.

Mr. Judson came to California in 1850 and went to the mines. After a year he went East and returned in 1852. It is said he started the first assaying office San Francisco ever had. In 1855 he became interested in the San Francisco Chemical Works and the manufacture of acid. Years ago he invested in hydraulic mines in Nevada and Butte counties, and was the first man to successfully carry water through a wrought-iron pipe passing down one side of a ravine and up the other under a 900-foot pressure. He made his own engineering calculations for this inverted siphon, and the credit of its success was wholly due to him. He was still interested in hydraulic-mining up to his death, being one of the principal owners in the North Bloomfield mines, the largest hydraulic mines in the State. He was the principal owner in the Kennedy mine, Amador county, now the leading gold-producer among the quartz properties of California. As showing Mr. Judson's willingness to advance a variety of interests, the following are given as a few of the enterprises in which he was a large owner: Judson Manufacturing Company; Judson Dynamite and Powder Company; California Paper Company; Western Fuse and Explosives Company; San Francisco Candle Works; San Francisco Chemical Works; California Pulp Works; Sather Bank; Pioneer Pulp Company; chemical works at Newark, N. J.

In the powder business of this city Mr. Judson was a most prominent factor. He was one of the originators of the Giant Powder Co., the first to manufacture high explosives on this coast. Not long after he invented and patented the Judson powder for bank-blasting, a substance which soon displaced others in gravel-mining work. The original high explosives were composed of nitroglycerin and absorbents; but this powder consisted of particles of black powder rendered nonabsorbent by a peculiar process, mixed with nitroglycerin so that the nitroglycerin remained on the surface. Only a small proportion of nitroglycerin was used, but the powder was found to be

peculiarly effective. The sales of the new product were immense, and the substance was patented all over the world.

Only a few years since, Mr. Judson organized the Judson Dynamite and Powder Co., and built very extensive works on the bay shore in Alameda county, the largest powder works at the time on the coast. In forming this company he associated with him some of the most prominent men and largest mineowners in this State, all direct-

which has been successful and profitable from its inception. It was somewhat surprising that at his advanced age he should start such a large new industry and his business rivals were not pleased at his efforts in this direction, particularly as they resulted in such a sweeping reduction of the products manufactured.

The exact amount of Mr. Judson's estate is not known, but it is doubtless between \$2,000,000 and \$3,000,000. He was an unmarried man and leaves the estate to his

four nephews and nieces, who are to receive the income for ten years, at the end of which time the property is to be divided. It is the desire of testator that the executors and trustees shall continue business jointly with J. L. N. Shepard for ten years. A codicil dated October 5, 1888, provides that the above request is not to be construed as exclusive of any other partnership or joint venture in which testator may be interested at the time of his death, and the directors are authorized to continue any and all business in which testator may be a partner at the time of his death, with the same powers as himself if living.

This codicil well illustrates the absolute singleness of purpose of Mr. Judson. He simply did this so that the men associated with him in business would be put to no inconvenience because he was taken away.

Active work was an essential feature of Mr. Judson's career, and he kept "in harness" until the end of his life, yet he was a man almost 81 years of age. At the time of the explosion of the Giant Powder works at Fleming's point he was a short distance away and jumped in his huggy to drive over to the scene. The horse ran away with him, going toward the fire. Just then the second explosion occurred, and Mr. Judson was thrown violently to the ground, being not many hundred feet from the magazine. He was permanently deafened in one ear and received some internal shock which undoubtedly hastened his death.

ANOTHER lost-mine romance comes from old Mexico. It seems that old workings of mines have been found near Ures, Sonora, where rich ore was recently discovered. Now observers jump to the conclusion that the long-lost mines

from which the Aztecs obtained their treasure have been found at last. It seems that prospectors would rather run after mines which have been once found and then lost than hunt up absolutely new ones.

THE mine of Santa Maria de la Paz, San Luis Potosi, Mexico, is reported to be in bonanza. The output is 5000 cargass per week of ore running between 10 and 11 ounces per carga in silver and carrying, besides, a fair ley of gold. The pay-roll and general expenses amount to \$6000 per week, and the net profits, also per week, range from \$25,000 to \$30,000.

THE tin mill at Hill city, South Dakota, is now running at its full capacity—250 tons per day. The separator of the metal is said to be satisfactory.

AT King, Colo., four miles from Cassio, a dust explosion in one of the chambers of the coal mine killed 27 miners.

THE LATE EGBERT JUDSON.

ly interested in the development of the mineral industry of the coast. Their idea of joining together to manufacture blasting powder was the result of their determination to avoid the payment of the high rates previously charged for explosives. This company soon brought the price of powder down from 18 cents to 12 cents a pound. Mr. Judson had previously left the Giant Powder Co. and disposed of all his stock in it.

Simplicity of habits and mind were marked characteristics of Mr. Judson. Notwithstanding his great wealth, he never asserted himself or sought for any prominence. If he had a weak point in business, it was that he was a little too frank himself because he thought other people were equally honest. It was a hobby with him that the enterprises with which his name was identified should become successful and advance the manufacturing industries of California. He thought more of this than of the money they would make for him. His last enterprise, the Judson Dynamite and Powder Co., was his greatest, and one

Comment.

Mr. Voorhies has introduced a bill in the legislature providing for a uniform system of signals in mines in this State. It has been pointed out in the MINING AND SCIENTIFIC PRESS that there is a necessity for some uniformity in this matter. In different counties, and different camps in the same county, the signals used are such as the respective mining superintendents prefer. In consequence, men going from one place to another are liable to confusion in the matter of signaling or obeying signals and disasters frequently result. With a uniform system all over the State there would be less liability to accident than there is at present.

The miners of Tuscarora, Nev., and those of Austin, Eureka, Candelaria, Pioche, and even Virginia City, all in the same State, are in a bad way. A dozen other smaller mining towns and camps are also in a distressed condition owing to the shutting down of silver mines and the discharge of men. In every one of the camps the number of employed is comparatively few, and in some instances there is absolute distress. The men have been holding on in hopes of better times, until their money is expended and they can now get no work. Even if they can get away, there is no place to go where they can follow their vocation, as all the silver camps on the coast have more men now than they can employ. These Nevada silver miners are about in the same predicament as were the miners in the hydraulic mining regions of California when the gravel claims were shut down by process of law. They found their occupation gone, and for some years there was much distress, which to some extent still continues. Not only miners, but storekeepers, artisans, and all the people dependent upon mining operations, feel the effect of hard times in such cases. In some instances, cases of destitution are reported. These people have not brought this upon themselves by laziness or improvidence, but the conditions have resulted from the low price of silver and the consequent loss in mining operations. When the mines closed down and there was no work for the men, all sorts of business in the camps languished and no money could be made by any one.

The rush to the San Juan placers in Southern Utah still continues. A stage line has been put on this week between Flagstaff, on the Atlantic and Pacific R. R. (Santa Fe route), and the new placer fields. The stage trip will be made in three days. Some favorable reports continue to come in, and others less so. A Mr. Knebler, who was

sent out by the Board of Trade of Durango, Colo., has returned and says there is little to warrant the excitement. There is no scarcity of food, but there is some distress among those who went improperly equipped. He says no men are working along the river and many are anxious to return. In many instances men went in with nothing and are cursing the men who started the boom, as they gave up their positions in order to get into El Dorado, so called. This is only what was to be expected in an excitement of this kind. Those who are lucky laud the country, and those who find nothing curse it.

The U. S. Senate Committee on Mines and Mining has reported favorably to the Senate the Caminetti bill with Senator Felton's amendments. By the exertions of O. P. Berry of this State, who is in Washington, the following amendment has been adopted by the committee: "Any person or persons, company or corporation, their agents or employees who shall mine by hydraulic process in violation of the provisions of this act, shall be punished by a fine of not exceeding \$5000, or by imprisonment not exceeding one year, or by both such fine and imprisonment, in the discretion of the court." The word *must* has been inserted instead of *may* in Section 9 of the bill, thus compelling all companies to file a petition for permission to mine by the hydraulic process. Both these changes are obnoxious to the miners. In the penalty clause there should have at least been a proviso specifying that the penalty only applied to mines injuring the navigability of the rivers; but this makes it sweeping and covers all. There are many now mining without injury to any interest. The word *must* compels every hydraulic miner, whether he has his own restraining works or not, to petition for permission to work. Where they have already built satisfactory works, and are complying with the law, they should have been let alone. The bill as it has been changed, is not at all what it was when the Miners' Convention indorsed it, and it is not at all what the miners want. In the opinion of many, it will do the hydraulic-mining industry as much harm as good. A penalty clause was to be expected, but it should have, in justice, excluded all now conforming to the law and all who do no harm to navigable streams.

The Magnetic Variation at San Francisco.

Dr. Mendenhall, Superintendent of the U. S. Coast and Geodetic Survey, has authorized Prof. Davidson to publish for the benefit of surveyors, civil engineers and navigators the results of the late magnetic observations made by Mr. Fremont Morse, of the Coast Survey, at the Presidio station.

The Presidio station has been occupied by the Coast Survey parties since Davidson's first occupation in 1882, for the determination of the magnetic elements, especially for the variation of the compass which has nearly reached its eastern maximum limit. In former notices we have shown that the maximum would probably occur about 1893.

The observations are now made at this station yearly, or half-yearly, in order to be sure of determining closely the epoch of the maximum eastern variation.

This year the observations for the magnetic variation extended through five days in the beginning of November, and they give an average of 16° 40' 5" east, with a comparatively small probable error. This value is nearly five minutes of arc greater than the computed variation; and the observed value has been greater for the last three years. This indicates that the maximum variation will be several years later than predicted.

The observed value of the variation is the arithmetical mean between the greater variation of the needle about 7½ hours A. M., and the smaller at 1 o'clock, P. M. The average change in this period was 6' 9"; and by that amount the direction of a line would apparently differ if run by the compass in the morning, or in the afternoon.

The dip of the needle from five days' observations was 62° 28' 2", and the value has been nearly stationary for three years. The observed horizontal intensity was 5.4476; and the resulting total intensity computed from this and the dip is 11.78 English units, or .5433 dynes.

THE Magdalena placers, west of Hermosillo, Mexico, about which there is now some excitement, were discovered by two women, Mrs. Louise Leglerly and Mrs. Fortunata Ronslat, of the village of Magdalena. They were sharp enough to secure the title to 35 of the richest claims in the district, and are now outfitting them with machinery.

THERE is no abatement in the mining excitement near Ures, Sonora, over the rich gold finds made a few weeks ago. It is estimated the new camp now has a population of 15,000 persons, mostly Mexicans, with a few American prospectors from the southern part of Arizona.

Position of the Large Hydraulic Mining Companies.

It may interest, and perhaps surprise, some of the anti-debris agitators of this State as well as the miners to know that the Caminetti bill, which was indorsed by the legislature on Monday, is really being opposed, not encouraged, by some of the largest hydraulic mining companies of California. The Caminetti bill provides for a California Debris Commission, and regulates hydraulic mining in California. It is this "regulation" which these larger companies and richer hydraulic miners oppose. At the recent State Mining Convention, after resolutions indorsing the bill had been passed, some of these men endeavored to have the resolutions reconsidered. They were unsuccessful, however, the convention indorsing the bill by a large majority. The richer mining companies and the richer hydraulic miners have always been lukewarm about this whole miners' movement. Both the financial aid and moral support given by them to the State Miners' Association have been exceedingly small as compared with their interests. At the first inception of the movement they came in but finding they could not have a bill drawn up for Congress exactly as they desired, they became lukewarm and have so continued.

The majority of the members of the executive committee of the State Miners' Association are fair-minded men, who desire to see the great hydraulic mining industry of California rehabilitated on lines which give some justice to its opponents; by methods which are fair to both sides, and in a way that no man's property need be injured. They have bent their energies toward conciliating the opponents of the industry, and toward carrying out the promises made at the State Miners' Convention of January last. They asked the hydraulic miners to immediately desist from illicit mining and wait for Congressional action which might permit them to work legally. When they found they could get no broader measure than the Caminetti bill, they worked to get that passed, as it at least, legalizes hydraulic mining and places the miner who works in good faith, on a lawful basis in his operations.

The larger companies and more prominent (because richer) hydraulic miners do not like this bill, and would prefer to have it killed and rest on the decisions of the courts alone.

The great mass of miners in this State should understand this situation. There are on the executive committee of the State Miners' Association only a few who have a ten cents' worth of interest in any hydraulic mine in California. They are, at least, unselfish in devoting their time to the cause. None have received a cent of money for their time or labor; even the secretary has been without salary for six months past. The association is not for hydraulic mining alone, but that special interest being in the greatest trouble has been given the most attention.

The reason the larger companies object to the Caminetti bill is, that under the present conditions they can build restraining works in any way they like and run the mines to suit themselves, provided they let no slickens into the rivers. Under the Caminetti bill such works would come under the supervision of the Government engineers. Each company or individual must file a petition with the U. S. Commission, and the owners or companies must surrender to the United States the right and privilege to regulate by law the manner and method in which the debris resulting from the working of the mine shall be restrained.

In other words, instead of putting up such works as they like, the companies must adopt the plans of the U. S. Engineers, and conduct the mine as the commission dictates as far as restraining debris is concerned. Moreover, hydraulic mining, directly or indirectly injuring the navigability of the river system of the Sacramento or San Joaquin carried on in that region other than as permitted by the provision of the act is prohibited and declared unlawful by the Caminetti bill. The larger companies argue that under recent decisions they can continue mining in their own way provided they keep the debris out of the rivers; while under the Caminetti bill they must submit to Government control and direction in the matter of their restraining works.

There are quite a number of miners now operating in this State with restraining works, to their own satisfaction, the owners of which do not wish to be compelled to come under any outside authority, control or supervision, such as is enforced by the Caminetti bill. These are all large operations, and it is such companies as these that object to the measure now pending in Congress.

W. P. LIPP, of Wheatland, while prospecting at Nugget ravine, seven miles east of Wheatland, on Frank Hunt's land, found a large gold nugget which weighed 14 ounces, 13 pennyweights and 8 grains. It is valued at \$246. Grundy Hendrix, while working on the same claim about two years ago found another large nugget for which he received \$236.

The Legislature Indorses the Caminetti Bill.

In the Assembly on Monday last, Price, of Butte county, offered the following:

WHEREAS, The interests of the State of California demand an immediate solution or a satisfactory adjustment of the hydraulic and river interests in this State; and

WHEREAS, Two State conventions, composed of representatives of all industries therein, have so agreed, be it

Resolved, By the Assembly of the State of California, the Senate concurring, that the Congress of the United States be hereby urged to speedily enact the measure known as the Caminetti House bill, relating to hydraulic-mining and river improvements in the State of California, or some other measure which in the judgment of that honorable body will serve the purpose set forth in said Act.

Resolved, That the Governor is hereby requested to affix his official signature to these resolutions and cause a certified copy thereof to be forwarded by telegraph to our representatives and senators in Congress.

Mr. Price explained that the bill would come up in Congress on Tuesday, and for this reason he desired immediate action, as it was intended to give the California delegation in Congress all the moral support possible. Vann, of Colusa, and Glenn and Durst of Yuba, opposed the resolutions on general principles. Vann made a long speech about the horrors of slickens and fear of the resumption of hydraulic-mining. Anderson, of Sacramento, wanted further time to consider the resolution, and Miller, of Alameda, wanted to know what the Caminetti bill was. Price thought everybody in California knew that. He briefly explained that the bill was designed to provide measures for the resumption of hydraulic-mining without injuring farmers and other landowners. Shanahan made a strong and clever speech in support of the resolution. He said immediate action or none was demanded. The Caminetti bill was not calculated to pull down or destroy, but to build up, to develop the State and add to the prosperity of the people. He spoke of the opposition which the antidebris people had made to every measure relative to hydraulic-mining, and gave as an instance the bill repealing the law declaring the Klamath river navigable, which, though it affected only three counties that were in favor of it, was fought hard by the valley representatives. The Caminetti bill had been indorsed by the two mining conventions, and the press has been in favor of it. Congressmen Caminetti and Geary, who favored the bill, were elected by large majorities in ordinarily Republican districts.

Mr. Shanahan, of Shasta, made an earnest speech in favor of the miners. He said there had always been opposition to every measure for their relief that had ever been introduced into the legislature, whether it affected the farmers or not. He said he could count the opponents of the bill in the legislature on his ten fingers, and urged the immediate passage of the resolution. Mr. Thomas, of Nevada county, also made quite a lengthy speech in favor of the resolution. O'Keefe, of San Mateo, stopped the debate by insisting on the previous question, and the resolution was carried by a vote of 73 to 5. On motion of Shanahan the resolution was ordered printed, and was immediately transmitted to the Senate.

Mr. Ford, of Sierra, chairman of the committee on mines, introduced the resolution into the Senate. Senator Ostrom, who has always been opposed to hydraulic mining, voted for it. In explaining his vote he said: "I will vote for the resolution, believing the Caminetti bill to be meritorious for the protection of our navigable waters and the protection of the lands adjacent thereto, as the bill places the old subject matter of the debris question in the hands of the War Department. That department has, to my knowledge, never been accused of partiality, wrongdoing or boodling." The resolution was adopted with only eight dissenting votes.

This action shows that the people of this State are in earnest about seeing hydraulic mining resumed, if it can be done without material injury to the rivers or other interests. The Caminetti bill provides for this, and while it is not entirely satisfactory to the miners, it at least legalizes hydraulic mining and provides a means by which it may be carried on.

A TRAIN of burros coming from the Las Animas mine, Mexico, loaded with silver bars, has lost one of its number. The lost burro is valuable, as he has on his back \$5000 in silver bars. There is another chance for the prospectors who are always hunting up "lost mines."

THE recent reduction in force by the various mines of Park City has apparently created a dearth of mining news, for there seems to be nothing at all going on. The prospectors have nearly all knocked off, and very few plans are being laid for the future.

A FURTHER reduction in force took place at the Anchor mine, Park City, Utah, on the 1st, 16 men being laid off on that date. Matters were made still worse by the shutting down of the concentrator, which threw 18 more men out of employment.

EIGHT HUNDRED miners were laid off for the present at Aspen, Colorado, last week, in consequence of the low price of silver.

Foundry Notes.

The Joshua Hendy Machine Works, of No. 51 Fremont street, reports that business for the new year has commenced auspiciously, and that their sales since its advent comprise a large boiler and engine shipped to San Jose, Cal.; also one Erie center crank engine, Buffalo duplex steam pumps, 15 "Challenge" ore feeders, several thousand feet of lap-welded wrought iron tubing for irrigating uses; a number of giants for hydraulic mining work; one 5-foot "Huntington" mill with all of its accessories of ore feeder, concentrators, etc., shipped to Mexico, together with several mining cars. They have in process of construction and shipment several "Climax" band-saw mills for use in the lumber districts of this and our sister States, and, as well, many other of their specialties, such as horse whips, etc.

The Pacific Laundry Machinery Co., under the management of Mr. J. E. Chappell and measurably under the control of the Joshua Hendy Machine Works, report that they have received the contract for furnishing the Veteran Soldiers' Home at Yountville, Cal., with a full equipment of the latest improved forms of laundry machinery; that they are further supplying a complete plant for use in Oakland, and another to be erected in Haywards; another complete new plant for use in Albany, Oregon; and still another for the St. Nicholas hotel in the Doe building, on the corner of Hayes and Market streets.

The Vulcan Iron works of this city have closed a contract with the Gambrinus Brewery Co. of Portland, Or., to furnish a 35-ton Vulcan horizontal refrigerating machine, with Corliss engine. These same works built last summer at Port Essington, on the Skeena river, British Columbia, refrigerating works for freezing salmon for shipment. The works have been shipping frozen salmon to New York and this week shipped the first carloads of frozen salmon to London, England. They intend also shortly to begin shipments to Spain. Nearly all the canneries will adopt this plan before long.

Col. R. H. Savage, formerly of R. H. Savage, Sons & Co., foundrymen of this city, has accepted an invitation to deliver lectures this winter at Yale University, before the Sheffield Scientific School and also the Vanderbilt Railroad Club of New York.

Irving M. Scott, who is in Washington, is well pleased with the result of the Monterey's trial trip. The Union Iron Works telegraphed the Navy Department that the run was most successful and exceeded the contracts in all particulars. The gratifying reports of the last day's trial incline the officials of the department to believe that it will be accepted as final and that the board will proceed to work up the result immediately. It is believed the builders will earn a large premium.

Secretary Tracy, as had been expected for some time, has awarded the contracts for both the new battleship and the cruiser to the Cramps. He issued a statement in which he explained that he thought both the Union Iron Works and the Cramps were excellent builders, and that nothing would please him better than to divide the contracts, but the law gave him no discretion.

Coast Industrial Notes.

THE salmon cannery at Chilcat, one of the largest canneries in Alaska, has been destroyed by fire.

THE work on the electrical engineering building at Berkely is progressing finely. The walls of the first story are nearly finished.

A COMPANY has been formed for the purpose of raising oysters in the bay at Anaheim Landing. An experiment has been made on a small scale with satisfactory results.

IN the legislature, Bledsoe has offered a bill regulating the hours of labor in sawmills, shinglemills, shakemills and logging-camps, fixing the limit at ten hours a day.

THE big lumber raft sent to this city by the Fort Bragg Lumber Co. was towed down by the steamer Noyo in 36 hours. The raft contained over a million feet of lumber.

REDLANDS during 1892 spent \$145,000 for sewers, sidewalks and drains; \$411,000 for canals, pipelines, reservoirs and streetcars; \$141,000 for business blocks and \$225,000 for residences.

ANOTHER big irrigating reservoir is to be built in Arizona. The new company is called the T. E. Farish Reservoir and Canal Co., and it has been incorporated at Phoenix. Most of the capital has been subscribed by Eastern men.

THE Amador Electric Light and Railroad Company broke ground last Saturday for the new electric road that will ply between Sutter creek and Ione city. Several men are now grading, and rails are arriving on the surveyed route.

The matter has provoked much comment. The pottery trust says the Council's proceeding is illegal, and threatens court proceedings. The aldermen say they passed the resolution because they thought they had a right to protect home industry against any trust.

WORK on a five-mile extension of the California and Nevada narrow-gauge railway will be commenced within a few days at the present terminus at Bryant, which is 22.8 miles from Emerys, Alameda county, where the line begins. The extension will bring the road to the middle of the tract known as the Moraga ranch, and it will run in the direction of Walnut creek.

THE largest logging contract ever let in Washington was signed at Tacoma this week between the Tacoma Mill Co., Allen C. Mason for the Shelton and Southwestern Railroad Co. and Frank Williamson. The latter is to cut and the railroad is to haul 200,000,000 feet of fir timber off the mill company's timber lands in Mason county, Washington. The logs will be sawed here and a large part of the lumber shipped to San Francisco, where the

mill owns a large yard. The steel has been ordered to extend the railroad farther into the timber belt. It will require five years to execute the contract. The freight on the contract will amount to \$250,000.

A PETITION signed by 400 citizens has been presented to the San Francisco Board of Supervisors, asking for the city's proper representation by an exhibit at the World's Fair, by an appropriation of a sum sufficient on the next tax levy for that purpose. There is already a San Francisco World's Fair Commission, but it has been unable to do anything for lack of funds. If the city is to be represented at all, the money should be forthcoming at once.

TRACK-LAYING on the new Potrero electric road has been completed on Kentucky street from the car stables near Second avenue to the Fourth-street drawbridge. Work is now being pushed on the last-named street and is expected to be finished about the end of the present week. It is intended for the present to use horsecars on the Kentucky-street line until the other two branches of the system through the Potrero, Southern Heights and South San Francisco districts are built.

THE San Francisco whaling fleet is getting ready for sea, and next month will see the greater number of the steamers and barks at present in port leave for a cruise in the Japan sea. They will after that rendezvous at Honolulu before proceeding north. The steamer Orca and the bark Wanderer have come off the Union Iron Works dry-dock and gone to Center-street dock to fit out for the cruise. The steamer Beluga has gone to the Union Iron Works dock, and the work of preparation is progressing on every side.

J. W. MORRIS of Oakland has been granted a franchise to build an electric street-railway line by the City Council of Santa Rosa. The proposed line will touch the San Francisco and North Pacific road on the west side of town. From there the new line will run up Fifth street to Mendocino; from there on Fourth to North and Thirteenth streets to McDonald avenue. There is considerable activity in street-railway circles in Santa Rosa. The Central Company is building an important extension, and the Union Company is preparing to build a line to Taylor Springs.

THE combination of pottery manufacturers, in trying to "freeze out" the Stockton Terra Cotta Co., is offering sewer pipe at one-third the price it was a year ago in that city. The local company complained to the City Council that it was in danger of being compelled to shut down if not protected. The City Council has passed the following resolution:

Resolved, That from and after this date no vitrified iron-stone pipe shall be used in the construction of underground sewers in the city of Stockton unless such pipe be of the same kind and quality as that now made and manufactured by the Stockton Terra Cotta Co. of Stockton.

At a meeting of Alaska salmon cannery men it was decided to combine permanently for mutual protection, and this week articles of incorporation will be filed of an association with a capital of \$6,000,000. W. B. Bradbury will probably be the secretary of the combination. The Alaska salmon cannery men did better last season than in many years. The market was overstocked two years ago from the pack of the previous season, and the cannery men decided to combine and limit the pack in 1892 to about 400,000 cases. Old stocks were cleared off in England and canned salmon brought a good price. The pack for this year will be limited to about 650,000 cases.

THE first report of the commissioners having in charge the arrangement of a sewer system for the city has been filed with the supervisors. It recommends the construction of a brick sewer in Scott street, to run northward from Pacific avenue, and from there a pipe sewer to form connections between Broadway and Vallejo street; that a sewer be laid in Filbert street, extending from Scott to Steiner, and that overflows be constructed on Broadway, Vallejo, Green and Union streets. It also recommends that the petition of property owners for the establishment of grades on Merced, between Laidley and Thirtieth streets, and Laidley, between Thirtieth and Merced streets, shall be granted.

A BILL will be presented in the State legislature providing for the purchase of land and the erection of a public building in San Francisco. This building is intended to accommodate the Supreme Court and Court Commissioners, the Hastings Law College, the Railroad Commissioners, Bank Commissioners, Board of Forestry, Bureau of Labor Statistics, Commissioner of Immigration, Insurance Commissioner, State Mineralogist, Yosemite Commission, and the Board of Arbitration. The Governor is to appoint three commissioners to select the site and oversee the erection of the building. Three hundred thousand dollars is to be the limit of the cost of the site, the building, the fee of the attorney and the compensation of the architect and superintendent of construction.

THE Telegraph-avenue electric road in Oakland has now been in operation two weeks and everything has been run in perfect order. The system was a complete success from the start. The Southern Pacific is the only company that has a horsecar line in Oakland. The corporation owns the old line on Twelfth street from Broadway to Thirteenth avenue. The road does not begin to pay expenses at the present time, as the people prefer to ride on the electric cars. The company will make this system into an electric road as soon as they can get an extension of their franchise to Twenty-third avenue. It is probable that the road at the west end will be extended to West Oakland. If they continue down Twelfth street to West Oakland there will be plenty of cars from end to end of the city. There are now lines running on both Fourteenth and Sixteenth streets, one being built on Eighth and one contemplated on Tenth. There are no odd-numbered streets in that district, so that, with the steamroad on Seventh, if all these lines are built, there will be one on every street from Seventh to Sixteenth.

An excursion steamer was launched from White's shipyard at Alameda point on Sunday. The new steamer is

called the Rosalia and will register about 250 tons net. The engines, which are compound, have cylinders of 15 and 34 inches, with a stroke of 24 inches, and will drive the steamer, it is expected, about 16 miles an hour. The dimensions of the vessel are as follows: Length over all, 141 feet; keel, 135 feet; beam, 26 feet; depth of hold, 10 feet. Only the hull is completed. After the launch the new steamer was towed to Folsom pier 2, where the engines and boilers will be immediately put in. The cabins and upper works were ordered from the East and are now on their way here. The steamer is designed for a pleasure boat and will accommodate 400 excursionists. The Rosalia is to be used on daylight routes. The steamer is a novelty of her kind. The facilities for preparing meals and the dining-tables in the main saloon will be extensive. It is expected the steamer will cost between \$75,000 and \$80,000, and will be ready for service by April 1st. The projectors of the enterprise are J. J. Ebert and C. L. Dimon Jr., who came here from Denver, Colo., some time ago.

Reduction in Freight Rates.

The Southern Pacific Company formally announces the following reduction in freight rates to meet clipper-ship competition: Beans, in carloads, from California terminals and points on the Ventura division to all points east of the ninety-seventh meridian on the Atlantic system to and including the New Orleans, but not including the Houston and Texas Central Railroad, \$15 a ton. Beans, from points on the Ventura division to New York only, \$13 a ton; from San Francisco to New York, but not from intermediate points, \$10 a ton in carload lots. Borax, San Francisco to New York only, in boxes, barrels or sacks, \$10 a ton in carload lots; from San Francisco, Oakland, Alameda, Sacramento, Los Angeles, Reno and points intermediate thereto to all points east of the ninety-seventh meridian, \$15 a ton. Wine, in wood, \$10 a ton, that is in carloads, from San Francisco to New York only; from San Francisco, Oakland, San Jose, Stockton, Sacramento, Santa Rosa, Napa, Vina, Marysville, Los Angeles, San Gabriel and intermediate points in California to all points East, to and including New Orleans, \$15 a ton. Brandy from the same points, \$17 a ton. Brandy, in wood, from San Francisco to New York only, \$12 a ton in carload lots. Canned goods, from San Francisco to New York only, \$10 a ton. From San Francisco, Oakland, Sixteenth street, San Jose, Stockton, Sacramento, Santa Rosa, Napa, Red Bluff, Los Angeles, Colton and intermediate points in California to all points East, \$15 a ton. Wool, from San Francisco only to New York and Boston, in grease compressed to nineteen pounds per cubic foot, in any quantity, \$1 per 100 pounds if valued at 10 cents per pound; \$1.25 per hundred pounds if valued over 10 cents and \$1.50 per hundred pounds if valued higher than 14 cents. The rates via the Central Pacific, Union Pacific, Denver and Rio Grande and the Chicago, Rock Island and Pacific from California common points to all points east of the ninety-seventh meridian on the Rock Island, not including points north of Fort Dodge, Ia., or west of Liberty, are as follows: Wine in wood, carloads, \$15 a ton; brandy, \$17; canned goods, \$15 and borax, \$15.

A BRITISH COLUMBIA TUNNEL.—The Nelson Miner says: Mr. Johnson, representing the Schaeffer Gold and Silver Mining Company, of Washington, has completed his arrangements for the purchase of the Mamie, Hamburg and Lady of the Lake claims at Ainsworth. He has also located two claims on the waterfront. It is his intention to run a tunnel in from the level of Kootenay lake to tap the ledges on these claims. During this winter work will be carried on by hand, and a contract has been let to D. W. Clark, Alexander McLeod, Milton Luther and Tom Garvey, all of Ainsworth, to run 300 feet of the tunnel, the work to be completed by the 1st of April, 1893. An air-compressor drill will then be put on and the tunnel pushed to completion. It gives some idea of the magnitude of the enterprise when it is borne in mind that the tunnel will pass under Loon lake at a depth of 1200 feet. Mr. Johnson expects that the company will expend about \$25,000 in tapping the ledges. He is much exercised over the duty on mining machinery. Air-compressor drills are not manufactured in Canada at all, and yet a 30-per-cent duty is exacted on their importation. This tax is calculated to injure mining interests and benefit none. It is the same with the other machinery required. More suitable machinery can be procured in San Francisco than on this side of the line, but the budding industry of mining must be handicapped in order that some manufacturer may have a ready-made monopoly to drop into when the time comes.

THERE is no longer any doubt but that the deposit of zinc in the vicinity of Hillsborough, N. M., is practically worthless. The ore bore such a close resemblance to zinc as to deceive several experts and it was not until the ore had been thoroughly tested that it was found to contain so small a percentage of zinc as to be of no commercial value.

A DISCOVERY has been made at the Unica mine at Angels, Calaveras county, of a pocket so rich that a 28-pound piece of rock yielded 16 pounds of gold; another piece weighing five pounds beld three pounds.

A. EKMAN is busily engaged in preparing and classifying the various ores and minerals he has received from Butte and Lassen counties for exhibition at the World's Fair.

MINING assessments falling delinquent in January amount to \$280,700, of which Nevada mines want \$270,700 and California mines \$10,000.

TWENTY-SIX days' run of the five-stamp mill of the Ashland, Or., Mining Company cleaned up 426 ounces of gold bullion.

Talc and Its Uses.

About 15 years ago a deposit of singularly pure fibrous talc was discovered near Gouverneur, N. Y., and the paper-makers of New England and Pennsylvania began to use it in place of sulphate of lime and clay as an adulterant for paper. The talc, says Stone, was found to have a strengthening effect by binding the fibers of the wood pulp together, and the use has increased until now nearly half of the good printing paper has talc, or something similar, as a filling matter. In the cheaper grades powdered soapstone, an inferior quality of talc, is used, and large quantities of it are annually consumed in the process. The Gouverneur talc is the finest in the world, probably, combining the brilliancy of the North and South Carolina product, with the exceptional fibrous quality of the Virginia variety.

The town of Gouverneur is near the northwest edge of a geological island of granite, gneiss and limestone formations. Toward the west of the town, Potsdam sandstone abounds, and Trenton limestone prevails on the southeast border. The talc deposit is in the townships of Edwards and Fowler, varying in distance from seven to fourteen miles from Gouverneur. Its length is about eight miles and its width one mile. The termination is abrupt at both extremities, and the local experts say that none is ever found except under surface outcroppings. That being true the deposit is limited to the above size, and the sudden and complete change of formation precludes all possibility of finding additional deposits. The veins of talc are nearly always separated by granite and gneiss, varying from thin layers to several inches in thickness.

Since 1879 ten distinct quarries have been opened, some reaching a depth of 400 feet on the slope. The cost of quarrying varies from 60 cents to \$1.25 a ton and the land owners collect from 50 cents to \$1 a ton royalty. The cost of transportation, from the quarries to the mills, over some of the worst roads in the United States, is about \$1.50 a ton, making the total cost of production at the mill \$2.35 to \$3.75 per ton. The average annual production is about 51,000 tons.

The reduction from the roughly-quarried stone to the fine flour used in manufacturing, is not materially unlike flour-milling in principle, though varying greatly in the appliances employed. It is first passed through a coarse, next a fine crusher and lastly through two pairs of buhr stones. It is then loaded into cars and from 800 to 1600 pounds at a time put into an alsing cylinder six feet and one inch in diameter and from six to ten feet long. The cylinder is lined with porcelain brick and for one-third its volume filled with Greenland pebbles. For four hours, or less, maybe, the cylinder is revolved at the rate of 20 revolutions a minute, at the end of which time the talc is in the form of an impalpable white powder, somewhat resembling flour. A part of the talc, known as rensselaerite has hitherto been thrown away, the removal of the glistening particles being a too long and costly process, but the recent introduction of Cyclone pulverizers has made that easy, and the economy in power is very great.

The Aluminium Calendar.

Aluminium is slowly but surely finding its way into commercial and practical value. It has had the usual introduction, both of friends and critics, and has mercifully survived the cruelties of both, the one skinning it alive and the other attempting massacre by kindness. The fault has not been in the metal—that is, as it was made. The division of opinion has been with the users, who are not altogether of that primitive type. The science of metallurgy, though in itself as inexorable as arithmetic or gravitation, is as yet but fractionally understood, while in this, as in all other domains of industrial intelligence, there are always competitive interests to handicap every new discovery or commercial enterprise. In the case of aluminium it has suffered from the two extremes, with the fact remaining like a rock after a deluge that the granite is intact when the mud is out of sight. No fictitious merit can survive practical tests, and no misrepresentation can successfully ostracise any natural product. Aluminium has its place in mineral economy, and its ultimate service will be determined without prejudice, not on what is said of it, but what it is. In its practical uses, experience will be the jury. This is the final adjudicator and practically ignores all premature opinions. We may sin in advertising soap, but we cannot annul the merits of a metal. In this since the merits and demerits of aluminium are not only being canvassed but demonstrated, and while the intelligent uses of the pure metal or its alloys are necessarily progressive, its definite and original qualities are primarily established. In lightness, strength and attractive finish, it is already a factor where such qualities are a special desideratum with its deployment along the same lines increasing and continuous. In certain forms of marine architecture it is making remarkable headway, with an outlook for more extensive service. In household and camp equipage, in surgical apparatus and artificial limbs, and in home and office decorations it has an already established service, and we note among its later uses its use in architecture. A building is reported as having been planned in Chicago, in which there will be no exterior exhibit of wood, stone or brick. The entire exterior, with the exception of the plate-glass windows, is to be of aluminium, sheets of this silver-like metal to cover the walls from the ground floor to a 16-story eminence. This is certainly a new departure; with its success and attractiveness largely provisional, but whether complete or not in its results, it is certainly an indication of what may yet be attempted and perhaps accomplished in the architectural uses of aluminium.—The Age of Steel.

THE steamer Alexander II, Captain Alex McLean, is being fitted out as a sealer, and will be the largest vessel of the kind existing when she is ready for sea. Twelve hunters and as many sealing boats will be taken on the steamer.

British Naval Speed Rules.

A regulation issued recently by the British-Admiralty defines specifically the technical meaning of certain terms employed to indicate the speed to be used by the naval vessels of Great Britain under different conditions of service, and gives rules for determining the power at which the engines are to be worked in conformity to these technical speed terms.

The standard established under this regulation for any vessel is the full power authorized for such vessel during a brief period of the time devoted to her quarterly high-speed trials under service conditions and with natural draft. This standard is taken as unity and the power prescribed to be used at any other time is referred to it.

The classification adopted is as follows:

(a) The authorized power with natural draft is taken as the standard, or the unit. This power is to be used only during four hours of the quarterly passage trials of vessels, or in an emergency, and the air pressures to be used for attainment of this power are not to exceed, in the fire-rooms, one-half inch of water for cylindrical boilers and one inch of water for the locomotive boilers of torpedo gunboats, except when the boilers are fitted with automatic ash-pit doors, in which case these air pressures may be exceeded by one-fourth inch of water if necessary to obtain the authorized power.

(b) "With all dispatch" means the maximum power that can be maintained for 24 hours, and is to be considered as being four-fifths of the standard (a). The four fifths power is only to be employed in cases of great urgency.

(c) "With dispatch" indicates the maximum sea-going speed—that is, the highest speed which can be kept up constantly for days or as long as the coal lasts. The power prescribed for this speed is three fifths of the standard. When steaming "with dispatch" all the boilers are supposed to be in use, with the engine-room force doing duty in three watches, assistance being given from deck if necessary, owing to the coal being so stowed as not to be readily accessible.

(d) "With moderate dispatch" is to be understood as meaning that two-fifths of the standard power (a) is to be used.

(e) "Ordinary speed" is the term employed when one-fifth the standard power is to be used, and covers the conditions under which passages are to be made ordinarily.

(f) "Most economical speed" denotes the speed at which the greatest distance can be covered with a given amount of coal. This can only be determined by trial for each ship under varying conditions of wind and weather. This speed is to be adopted whenever the economical use of fuel is imperative and also in those cases where the "ordinary speed" is less than the "most economical speed."

The quarterly passage trial, to which reference has been made, is a trial executed once a quarter, except in the case of vessels engaged on surveying service. The object is to make sure that the machinery is kept in efficient order and to provide for the training of the engine-room force in working the engines at high speed. The trial consists of a passage of not less than 24 hours' duration, made "with dispatch." During each one of these trials the engines are run for a period of four hours at their highest speed with natural draft, care being taken not to exceed the authorized natural-draft power.

The use of the steam blast during the quarterly passage trials is prohibited and vessels fitted for using it are only allowed to resort to this means of increasing their speed in cases of great urgency and for short periods only.

Phosphate Rock.

Since the first use of the phosphate rock discovered in South Carolina it has furnished a large proportion of the phosphoric acid used in the manufacture of commercial fertilizers. It is found in masses varying from small sizes to fragments weighing 100 pounds or more and covers a considerable area near Charleston, in that State. More recently large deposits of this rock have been discovered in Florida, thus assuring an apparently abundant supply of one of the chief constituents of plant food at a cheap cost. The Carolina rock contains from 25 to 32 per cent of phosphoric acid, while the Florida deposits, so far as yet known, are more varying in their composition. To make the phosphoric acid in bones and phosphate rocks more directly available for plant use they are ground and treated with sulphuric acid, which combines with the lime and liberates the phosphoric acid, thus producing what are known as superphosphates.

CALIFORNIA PETROLEUM.—The business of prospecting for, raising and utilizing petroleum in California has during the year under consideration been prosecuted actively, and with a good measure of success, the total output of the crude material being estimated at about 500,000 barrels, say 20,000,000 gallons, a quantity unprecedented in the history of the industry in this State, where alone on the Pacific coast it has yet obtained a foothold. How rapid has been the recent growth of this industry in California is shown by the fact that the output of oil in 1891 amounted to only 350,000 barrels, the largest that had been made up till that time. The principal producing localities have been the several districts in Ventura and Santa Barbara counties, credited with 265,000 barrels; the Pacific Oil Company, operating near Newhall, Los Angeles county, 150,000 barrels; the Puente district, same county, 35,000; all other localities, 50,000. According to this showing, California ranks third in the oil-producing States, being excelled by only Pennsylvania and Ohio. At the same time the California crude oil sells for more than twice as much as it does in either of these States, there being here a great demand for it for fuel purposes.

What We May Produce.

Though we are shipping to distant parts both by ship and rail immense weights of produce and receiving therefor considerable sums of money, there are still deficiency items in local production of articles for home consumption. Of course these items are almost insignificant in comparison with the imports of food supplies which California needed in earlier years, and yet the saving of their cost, or rather the distribution of it among our own people would help out a good many individual incomes. Governor Markham wisely makes an allusion to this subject in his biennial message which went to the legislature on Tuesday of this week, and the statistics he gives are of interest. The quantities given are in tons weight of the articles mentioned, and they are presented merely as estimates, not accurate statistics, of imports into the State:

Live stock.....	40,000	Potatoes.....	3,000
Wool.....	1,500	Broomcorn.....	800
Hides.....	600	Flour.....	2,500
Cured meats.....	20,000	Other mill products.....	2,600
Poultry.....	1,000	Starch.....	1,600
Butter.....	2,000	Olive oil.....	150
Cheese.....	1,800	Honey.....	60
Eggs.....	3,500	Canned goods.....	6,000
Hay.....	15,000		

These quantities can be reduced or expanded in several ways to bring them within the adequate conception of the reader. Perhaps dividing by ten to bring the material into carloads will serve most minds best. We have then 4000 carloads of live stock brought into the State, and this would be about equal weight to the whole orange crop of California for last year. The weight of imported cured meats was about half as great, representing, however, a vastly greater live weight of animals. Continue the calculation as we may it will be all the plainer that we are still dependent upon adjacent or distant States for a respectable part of our food supplies which we could as well produce for ourselves. Think of a State in which well-kept poultry is as profitable as it is here purchasing from the outside 100 carloads of fowls and 350 carloads of stale eggs. Other things in the test are almost as interesting in their way.

We are not unmindful of the fact, of course, that much of this imported food comes from regions of cheaper lands than ours, and part, no doubt, from free ranges. Still there is good opportunity to overcome even such odds by a little closer study of the arts and economies of production. It is quite possible to make a respectable figure in turning wastes and by-products into desirable and marketable material, just as the most successful manufacturers do by close figuring and constant personal attention to details.

Such calculation is not consonant with California traditions, and yet if California continues as she has advanced during the last decade, she will become quite a thrifty State in the end. Of course, as long as boom products command boom prices there will not be serious thought of the small arts of production, but the tendency is the other way, and our people will ultimately learn how to squeeze a nickel so that it will fly into five pieces. We are not anxious for such a day, and yet when it comes we shall be found with greater accumulations and with a spirit of independence and widespread condition of forehandedness which will give us greater industrial strength.

Dredging the Salmon River.

However impracticable it may appear at first to the unthinking mind—this talk of dredging Salmon river for its concentrated treasure in the form of placer gold—yet a thinking man who has kept at all posted with regard to the recent steps taken in scientific knowledge, brought to successful issues through earnest investigations and experiments, cannot but acknowledge that by the use of the lately invented suction dredge, such a scheme would not only be feasible, but would bear the stamp of success on it from the start.

If once bedrock can be found, the nozzle of the dredger that will admit of the suction and passage of everything brought under its influence to the consistency of a pebble three inches in diameter, will ride over its surface in a semicircle, taking in, of course, a fresh swath, as it were, at each new anchorage.

All the larger boulders, of course, are cast aside, the nozzle being made in the form of a flange, convex, with corrugations that agitate the surface on which it is resting in accordance with the number of revolutions it makes per minute; powerful suction pumps attract the material to the deck of the dredge, where it is treated as suitable to its condition.

The principal rivers of New Zealand are being successfully treated in this manner at the present day. Enterprise is all that is needed to bring this industry to the front, and when once attempted, should the experiment prove that Salmon river bed contains enough of the precious metal to make it a success, he alone who first placed it there can be the judge as to how much our community will be benefited by it.—Salmon City Hydraulic Miner.

DEATH VALLEY'S BORAX TEAM.—One of the odd contributions to the World's Fair Mining Department will be what is called the Death valley borax team. It is contributed by the Pacific Coast Borax Company, and consists of a model in borax four feet high, a borax wagon loaded, and on its way over the desert from the famous Borax lake, California. The wagon, to which is attached a provision cart and water-tank, has hitched to it 20 mules. In crossing the dry plains about the borax deposits, it is necessary to carry sufficient water for both the men and the stock.

WM. J. COX who was for a long time superintendent of the famous Mollie Gibson mine, under manager C. E. Palmer, is now manager of that property. This Colorado mine paid twelve dividends in 1892 aggregating \$1,800,000, and has started the new year with the regular dividend of \$150,000.

Importance of the Mining Industry.

According to reports of the Bureau of Labor Statistics for Colorado, the number of laboring miners in the precious metal mines is 16,962. In the coal mines there are 6000, making the total 22,962. The number of teamsters, woodcutters, carpenters, blacksmiths, employes in mills and smelters, charcoal burners and laborers who are directly employed in supplying mines or hauling ore, amounts to 20,000. So that out of a total voting population of 92,000 over 50 per cent are engaged in work furnished solely by the mines. In addition to these are thousands of railway employes engaged in a traffic dependent solely upon the mines. There are other thousands engaged in manufacturing mining machinery, and other thousands engaged in manufacturing goods consumed by those who are supported by mining, and other hundreds engaged in merchandising which is supported by these mining people. And there are several thousand farmers who can farm at a profit only because the miners furnish them a market.

To understand the importance of this industry to the State, let it be supposed that every mine were to close down. The immediate result would be to throw 42,000 men out of employment, and their means of livelihood would be at an end. The manufacturers of mining machinery would have no market for their wares and they would close. The mills and smelters would be idle. The workmen would have no means to pay the grocer and butcher, the railways would have no freight traffic, the men who live upon their receipts from ore sold would be like the wage-workers, and how would all this affect business? What would real estate and railway property be worth? Who would buy the products of our cotton and paper mills and other factories? The inevitable result would be ruin, and the coyotes and jack rabbits would play hide and seek in Colorado towns and cities.

Of course such an event as the closing down of all the mines is not possible. But of the 895 producing gold and silver mines in the State, it is not impossible that a large proportion may close down. At least, over 700 of them yield silver as their chief product. Over 400 yield silver and lead. Whatever affects the price of either silver or lead affects these mines, and it is not impossible, or even improbable, that a decline in the price of either metal will close down many of these properties. Instead of throwing 42,000 men out of employment, a quarter or a third or half of that number may be deprived of work. While such an event would not bring ruin to the State, it would bring it to many thousand men, and would be a serious injury to all lines of trade.

We have used these figures simply to illustrate the importance of the mining industry to all the West; to call attention to the fact that it is the foundation stone upon which the whole business superstructure rests. It is a pretty good truth in engineering as well as all other things that the foundation must be sound, else the superstructure is likely to fall. It is to the interest of every man to aid in making the foundation sound.—Denver Mining Industry.

One Location to One Discovery.

Secretary Noble last week made an interesting decision, in which he canceled the patent of J. F. Bigelow for the Poplar Creek Consolidated quartz mine in Marysville district, and comprising the Pinenut and Gorilla locations, both made on the same day in 1888 and afterward purchased by Bigelow. The original discoverers and locators were D. M. Bell and Joseph Braden, who, in their location notices, failed to recite that they had discovered a vein or lode. They took up two full claims and started work on the division line of the two claims.

Secretary Noble says that good faith is required of those who locate lands for mineral and make entry thereof, and no valid location can be made unless there has first been an actual discovery. The law contemplates that the discoverer shall have the right to locate his claim to the exclusion of all others, and if the discovery is made by three parties, but one location can be made by them, as the first is the only single discovery.

"No man being rational," says the Secretary, "would discover a vein or lode and so describe the location as to make one of the end lines run through the center of the discovery shaft, thus leaving territory not located in which it was demonstrated that ore existed, and which might have been included in the description. In this case it is decided that it was one discovery made by two men and only entitled them to make one location."

"If the law could be so construed as to allow two locations in a case like this," concludes Mr. Noble, "it would also have to be held that one discovery would entitle the discoverers to make four locations, placing a one-fourth discovery to the credit of each, and the law is not susceptible of any such construction. A discovery is a whole, and may not be divided and parceled out among several discoverers."

MRS. PHOEBE A. HEARST has returned from her European trip. While she was in Europe Mrs. Hearst occupied herself in gathering information as to industrial homes for boys, with a view to the establishment of one for the destitute boys of California. Mrs. Hearst intends to establish such a home as a memorial to the late Senator Hearst. It will be erected on the 450 acres near Pleasanton, which the Senator once intended for a horse farm. The building will cost about \$200,000, and will be supplied with everything necessary to the industrial education of a number of boys from 8 to 16 years of age. The home will probably be self-supporting; but, should it fail to be, Mrs. Hearst will furnish the necessary financial assistance. It will be managed by a board of directors, but will be under Mrs. Hearst's personal supervision during her lifetime. A monument to Senator Hearst will be erected on the ground.

U. S. Branch Mint Report.

The coinage of the United States Branch Mint in this city during each month of the year ending November 30, 1892 was as follows:

Month.	Gold.	Silver.	Total.
December 1891.....	\$4,122,500	\$100,000	\$4,222,500
January, 1892.....	1,440,000	240,000	1,680,000
February.....	2,220,000	240,019	2,460,019
March.....	2,660,000	236,170	2,896,170
April.....	1,822,500	100,000	1,922,500
May.....	979,500	100,000	1,079,500
June.....	1,755,500	197,794	1,953,294
July.....	1,140,000	147,000	1,287,000
August.....	2,140,000	148,620	2,288,620
September.....	2,160,000	100,000	2,260,000
October.....	1,812,500	100,000	1,912,500
November.....	1,260,000	180,000	1,440,000

Totals..... \$23,512,500 \$1,895,703 \$25,408,203

Classified, the coinage of the past twelve months compares with the corresponding months of the previous year as follows:

Double Eagles.....	\$21,830,000	\$20,865,500
Eagles.....		1,155,000
Half-Eagles.....		1,492,000
Standard Dollars.....	5,190,000	1,206,000
Half-Dollars.....		444,514
Quarter-Dollars.....	554,000	159,020
Dimes.....	319,011	86,169

Total..... \$27,893,011 \$25,408,203

The branch Mint was established in this city in 1854 and its total coinage to November 30, 1892, was as follows:

Double Eagles.....	\$714,257,520
Eagles.....	55,237,560
Half-Eagles.....	59,026,040
Three Dollars.....	186,300
Quarter-Eagles.....	1,861,255
Dollars (Gold).....	90,232
Standard Dollars.....	79,275,073
Trade Dollars.....	26,647,000
Half-Dollars.....	14,533,739
Quarter-Dollars.....	6,121,845
Double Dimes.....	231,000
Dimes.....	3,875,894
Half-Dimes.....	119,100

Total..... \$961,462,558

Of the above amount \$830,658,907 was in gold and \$130,803,651 was in silver coin

Thirty-Eight Irrigation Districts.

L. M. Holt, editor of the *Rialto Orange Belt*, has just made an interesting compilation relative to the irrigation districts of the State.

It is found that 38 districts are now in working order throughout the State. There have been a number of others organized, but varied obstacles have interfered with their continued activity.

Three of the districts are in Colusa county, two in Stanislaus, two wholly in Fresno, three in Fresno and Tulare, three wholly in Tulare, one jointly in Kern and Tulare, five in Los Angeles, eight in San Diego, seven in San Bernardino and one each in Orange, Kern, Glenn and Yuba counties.

The 38 districts contain 2,149,724 acres; 19 districts report having voted bonds to the extent of \$11,834,000.

There are also 13 other districts that have voted \$4,942,000, and these districts have sold no bonds.

This makes a total of \$16,776,000 in bonds voted by 32 districts. There are six districts in the list that have not as yet voted any bonds.

The sale of bonds for cash amounts to \$2,622,000, and traded for water rights \$2,995,200, a total of \$5,617,200 in bonds disposed of out of \$11,834,000. The other districts are evidently not ready to sell their bonds as yet.

The assessed valuation of 28 districts is \$32,992,849. These 28 districts contain 1,515,594 acres and the assessed valuation is a little over \$21 per acre.

The 32 districts that have voted bonds contain 2,831,424 acres, and the bonded debt is an average of \$52 to the acre.

Of the 38 districts, the issue of bonds has been confirmed in the courts in 26 districts.

In 26 districts the report comes that the Wright Irrigation law is satisfactory to the people. Of course this means in a general way, subject to such amendments as may be deemed necessary. In one district the report is that it is unsatisfactory, in one district the report is doubtful, and the other districts are not heard from.

Black Hills Mines.

The mineral output from the various mines of the Black Hills for the year 1892, as far as can be ascertained, has been as follows:

Homestake.....	\$3,000,000
Golden Reward.....	445,000
D. & D. Smelter.....	700,000
Consolidated Plant.....	500,000
Welcome Plant.....	48,000
J. R. Mine.....	75,000
Big Missouri.....	35,000
Columbus Mining Co.....	63,000

In addition to this, many of the mines have shipped their ore to eastern smelters, and no definite statistics can be gained of its value. A conservative estimate would be \$1,500,000.

The following dividends have been paid by the mining companies of the Black Hills for the year 1892:

Homestake.....	\$150,000
Deadwood-Terra.....	100,000
Golden Reward.....	60,000
Monitor.....	22,000
Buxton.....	20,000

The Bacteriology of Poison Oak.

CLAREMONT, Los Angeles Co.

TO THE EDITOR:—What poison ivy is to the eastern States, poison oak is to the Pacific coast. By many the two plants are pronounced identical, the name *Rhus toxicodendron* being assigned to both.

The California variety attains a growth from two feet upward, not, however, to exceed a good-sized bush. It has a compound leaf of three leaflets, which are of a bright green color throughout the summer, but which change to beautiful red in the autumn. The bright colors allure the unsuspecting on till a bunch of the leaves is picked for the purpose of adorning some table or mantel-piece at home.

The poison-oak plant prefers as its habitat mountainous districts, especially canyons or the edges of creeks, but by no means is it found exclusively in those places. About each plant there seems to be a floating infection, a poisonous atmosphere, which, strange to say, has a variety of effects upon different individuals, the extremes being a painful inflammation, on the one hand, and but little or no effect upon the other; while between, lie all the possible gradations. The first sensation noticed, on being poisoned, is that of itching, which is usually accompanied by redness of the skin on the affected parts. The itching increases till it becomes almost intolerable, the skin smarts or burns, and swelling ensues.

Shortly, little protuberances appear, which increase in size till they break, yielding a transparent, sticky fluid called serum. The vesicles (as these protuberances are called) become covered with a crust and so endeavor to heal. The final stage, accompanying convalescence, is characterized by the peeling off of the cuticle on the affected parts, exposing to view the new, fresh skin underneath.

What is the nature of the poison that produces the unpleasant effects mentioned above? Is it vegetable, mineral or bacteriological—that is, produced by the ravages in the system, of microbes of disease? Such questions have confronted the investigator from time to time; and up to date, about the only results arrived at are expressed in some newspaper by a half-dozen words stating that poison of poison oak is due to germs. Doubtless, this is the truth of the matter, and it is the object of this article to present to the reader some of the evidences which sustain this truth.

The poison-oak plant is the favorite abiding-place or habitat of a microscopic germ which for the present we will call the poison-oak germ. There is nothing unusual in this, for we find similar phenomena on every hand. The white scale prefers citrus trees to feed upon; the potato bug takes to potato plants; certain plant lice prefer rose bushes; others would rather feed upon a different kind of bush; and so it goes, there seeming to be a special parasite for each plant. In the microscopic world we find the terrible bacillus tuberculosis feeding upon the lungs of unfortunate consumptives.

But we can reason in other ways better than by analogy, for if we take a poison-oak leaf and wash it in distilled water, we will find floating in the water little spherical jelly-like bodies. Bacteriologists term such sphere-like germs *micrococci* to distinguish them from cylindrical forms (bacteria) and rod-shaped forms (bacilli).

We must notice what we can about these micrococci, for we shall have occasion to refer to them again. If they are real, live germs, they should grow and multiply in any fluid upon which they can feed. Beef broth, which is usually used for cultivating and growing microbes of all kinds, has been tried, but so far has not succeeded. As they do live and thrive upon the juices of the poison oak, let us make a decoction of the roots and thus get fresh, wholesome material in which to breed them.

This decoction is completely sterilized by repeated boiling, after which it is placed in test tubes to the depth of one-half an inch in each test tube. These are set in a warm place for a few days, and if any cloudiness appears in the clear liquid at the bottom of any tube, it is to be discarded, as some unknown germ has succeeded in getting into it, and is beginning to multiply.

A tube with clear liquid inside may be used with safety as a culture medium for our poison oak micrococci. To avoid cultivating other germs which may be adhering to the outside of the leaves or bark, we shall dampen the point of a sterilized needle with the sap from a freshly made incision underneath the bark. The needle is at once transferred to the test tube, the cotton stopper replaced and the whole set in a warm place to await developments.

In a few days cloudiness is noticed, provided our inoculation was successful, and a drop of the liquid may now be examined with a microscope. If but one kind of germ is found, we may indeed be thankful, for we have a *pure* culture.

Let us examine the myriads of forms before our eyes carefully. We see sphere-like forms in every way identical with those found in the washings from the leaf. They are the progeny of a few forms we introduced when we dropped in the needle.

Now let us turn our attention to something a little different. We will make use of two persons who are susceptible to poisoning from the poison oak; that is, who "take it" easily. On the wrist of one, we will place a poison oak leaf for a second and then immediately bind on a cloth, the leaf being of course removed. The cloth prevents any rubbing or spreading by rubbing of any infection left by the leaf. The symptoms of poisoning at once set in—the itching, the smarting and the swelling—but it is noticed that the disease, if it may be called such, confines itself to the one locality; viz., where the leaf touched the skin. If cloth around the wrist has in any way slipped, say from right to left, the disease has spread in that direction, and to the same extent that the cloth has been displaced.

The second individual allows a leaf to be in contact with his hand for the same time as before, but instead of binding the place with cloth, he rubs his other hand over the

place, then rubs his face and both hands thoroughly. Shortly, itching, smarting, swelling, etc., have set in wherever he has rubbed. The palms of the hands seem to be unaffected, however, but where the skin is thinnest, there the effects are most noticeable.

Let us now draw some conclusions from our experiments upon the persons. That the poisonous effects are largely local is certain; so that, if persons who had touched the plant would refrain from rubbing their eyes and face and hands, many severe cases of poisoning would be prevented, as the affection, which is at first local, would not be spread to other parts, and hence increase the area of inflammation.

The micrococci, on being transferred to the skin, immediately penetrate the tissue beneath (unless the cuticle is too horny or thick, as in the palms of the hands), when wholesale destruction commences.

Why is it that some people will be affected by the poison oak plant to little or no extent, while others suffer so much? This is hard to answer with certainty. It is quite probable that the state of the system as regards degree of acidity has something to do with it. Some germs thrive best in acid media of certain strength, while others require less acid or even no acid, and some thrive best in alkaline solutions. The blood differs in different individuals, in one case being in the right condition to promote the most rapid multiplication of the germ, while in another case hindering the growth and development of the germ to a considerable extent. In many cases, if not all, the disease microbe itself makes a condition that causes its own destruction. This is by a secretion, or else by the resultant action of the secretion upon the tissues.

Often these products (called ptomaines) are exceedingly poisonous, but whether harmless or harmful to the human species, they become fatal to the microbes that make them when a certain strength is reached. For instance, vinegar or dilute acetic acid is a ptomaine, and when about 17 per cent is present where the germ is at work, the process ends, for at this point the germ is killed.

But nature does not wait for the self-destruction stage to come, for in some cases this would not be reached till after the death of the individual person. She has a standing army of little cells, which is found in all parts of the body. These cells are endowed with the power of locomotion and also with the power of digesting any foreign particle that comes in their way. They are especially on the watch for disease germs, as if they knew that these latter constituted the deadliest foes of their lord and master—the individual himself. When acting as defenders of the body the cells are termed *phagocytes*.

Now, when disease germs enter the living tissues at any place, the phagocytes in the vicinity of that place congregate and proceed at once to annihilate the intruders. The great number of the phagocytes produces a swelling and we say inflammation has set in.

The micrococci of poison oak on being transferred to the surface of the skin commence their ravages, and, if the conditions are right, will soon be in the delicate tissue beneath. Here the phagocytes are encountered and great quantities of them pour in from all sides. A miniature battle ensues, the germs multiplying as fast as they can and tearing down the tissues, and the phagocytes eating them up with all possible haste. If the microbes win, the person dies; if the phagocytes win, he lives. The phagocytes conquer in poisoning from poison oak, but thousands of them are killed. The sticky serum from the vesicles formed during the course of the disease contains phagocytes, and we should be able to see the micrococci which they have eaten inside of them. Upon examining some phagocytes found in the serum we will notice the micrococci present, and they are like those we saw as coming from the surface of the poison oak leaf.

What a touching sight it would be if we could but see our faithful little phagocyte servants fighting for us to their own destruction! They are not *things*, for they eat, move, digest, generate cells like themselves, and, when the time comes, die, and are carried off by the blood.

Now let us make one more examination. Take a small fragment of the skin which peels off during convalescence. Place it in a drop of distilled water and put it under the microscope. The skin that has peeled has been the seat of action for the spread of the micrococci for a week or so, and therefore should be pretty well impregnated with them. Surely enough, myriads upon myriads of forms that are no different from those we have examined before, now appear before the eye. If such fragment of skin should contain so many, what countless millions would be found in the flesh of one's hand or face.

We see, then, that we may become the feeding-ground, so to speak, of the micrococci and furnish to them at our own expense, material with which they can propagate themselves.

But are the poisonous effects due to the micrococci directly, or are they due to the ptomaines they make? This is a question. The floating infection which exists in the neighborhood of poison oak plants or bushes may be the volatile ptomaine, but even then some of the germs must be present, or so many would not be found on the skin during the disease.

However, it is evident that the micrococci are either directly or indirectly the cause of the poisonous effects.

In the autumn, when the sap goes to the roots and the leaves turn red from oxidation, the germs seem to lose a large part, if not all, of their injurious properties. This of course is probably due to the lack of sap upon which to feed and a consequent change of state in themselves.

Remedies too numerous to mention are used by the people of the Pacific coast to diminish the inflammation in a case of poisoning. The ideal remedy would be that which would destroy the micrococci upon simple contact with them, and at the same time be perfectly harmless to the flesh. Most of the substances now used are used for the purpose of decreasing the inflammation, and one of the best of these seems to be the sugar of lead in solution, bathed upon the affected parts, but handled carefully, as it is an active poison. While every one east of the Rockies is awaiting the remedy which will stop the ravages of the

cholera, the yellow fever, or the smallpox microbe, let us be on the lookout for something which will destroy the less fatal but troublesome micrococcus of the poison oak.

F. H. BILLINGS.

Quicksilver.

An Increased Production During the Last Twelve Months.

During the 12 months ending November 30, 1892, the receipts of quicksilver at this port aggregated 20,969 flasks valued at \$891,182. The receipts during each month during the past two years were as follows:

Months.	1892. Flasks.	1891. Flasks.
December	1,287	1,304
January	1,701	1,663
February	1,543	1,011
March	1,875	866
April	1,901	1,072
May	1,598	1,047
June	1,614	1,031
July	1,632	1,166
August	2,013	1,099
September	1,753	944
October	2,171	1,751
November	1,881	1,522
Totals	20,969	14,506

The exports by sea during the 12 months were not large as compared with the receipts, but the aggregate is nearly twice as large as the total for the preceding 12 months, as shown by the following figures for each month:

Month.	Flasks.	Value.
December, 1891	138	\$ 5,865
January, 1892	637	24,574
February	2,145	90,182
March	594	23,533
April	385	15,817
May	541	22,915
June	471	20,504
July	773	32,847
August	146	5,704
September	462	19,233
October	594	24,948
November	310	12,690
Totals	7,196	\$298,812

The exports of the year were distributed as follows:

	Flasks.	Value.
New York	3,318	\$142,365
Mexico	2,689	108,267
Australia	778	31,634
British Columbia	42	8,535
Central America	215	1,669
New Zealand	160	6,467
Totals	7,196	\$298,812

The export trade of the year by sea compares with the two preceding years as follows:

	Flasks.	Value.
1891	3,869	\$167,694
1890	3,516	176,268

The product of the past year and of all the California mines from 1877 to 1892, both years inclusive, comprising a period of 16 years, is as follows:

	Flasks.	Flasks.
1877	79,395	1886
1878	63,880	1887
1879	73,684	1888
1880	59,926	1889
1881	60,851	1890
1882	52,732	1891
1883	46,725	1892
1884	31,913	
1885	32,073	Total
		697,724

The production of all the mines during each month of the past year and for the 12 months preceding is as follows:

December, 1891.....	Flasks.....	July.....	Flasks.....
January, 1892.....	1,704.....	August.....	2,169.....
February.....	2,474.....	September.....	2,251.....
March.....	2,303.....	October.....	1,991.....
April.....	2,373.....	November.....	2,707.....
May.....	2,271.....		2,718.....
June.....	2,141.....		
	2,079.....	Total.....	27,259.....

The product of each mine from January 1st to December 1, 1892, and for the whole term of 16 years, from 1877 inclusive, is as follows:

	1892. Flasks.	1877-92. Flasks.
New Almaden	5,210	302,867
Attna	1,150	46,270
Napa Consolidated	5,340	28,609
Great Western	5,522	59,142
Sulphur Bank	1,280	73,426
New Idria	758	35,392
Great Eastern	1,515	18,465
Redington	628	33,876
Bradford		10,397
Guadalupe		45,189
Lake	526	526
Mirabel	2,790	2,790
Abbott	636	636
Various	200	38,487
Totals	25,555	696,020

The total dividends declared by quicksilver mining companies during the past year amounted to \$162,500 of which the Great Western Company disbursed \$112,500.

The Season of Mining Booms.

Now is the season to start mining booms, says the *Pioche Record*. With snow on the ground from two to ten feet where the mineral has been reported found, the dead beat who "discovered" the wonderful place is pretty sure of his lies not being found out until springtime. In the meantime he is living on the fat of the land at the expense of gudgeons whom he is to "let in" on the wonderful discovery. But when the snow vanishes in the springtime, so does the "prospector," to repeat the story in another part of the country next season.

Mechanical Progress.

The Electric Motor and Machine Design.

Two or three years since, says the *Iron Age*, it would have required a careful search to find an electrically-driven traveling crane, and yet now they are a part of the equipment of almost all of the new shops and also of remodeled old ones. This industry has become so important as to cause the establishing of concerns for the special manufacture of electric cranes, and has compelled makers of other styles of cranes to add this branch to their business.

We find that the electric motor, as applied to the driving of machine tools, is now in its evolutionary stage. It is forcing its way into the machine-shops, but with only two or three exceptions it appears merely as a special appliance intended for some particular operation. In the De La Vergne erecting-shops, recently described in the *Iron Age*, electric motors furnish all the power needed, and the same is true of the extensive establishment of Fraser & Chalmers of Chicago, who now have an aggregate of some 350 horsepower in electric motors distributed through the works.

The electric motor has proved to be as reliable as, and more economical than, the lineshaft. The electricity is conducted from the dynamo to the motor without an appreciable loss, and when the motor stops, there is no loss because of useless motion. Having these decided and accepted advantages, we must look to other causes for its comparatively insignificant employment. Of these we shall consider but one, which is, we think, the chief—the high speed of the motor itself. To apply the motor to the running of large tools such as lathes, planers, boring-mills and the like, where the cutting speed is very low, one of two things is necessary—either we must employ countershafting between the motor and machine to reduce the speed, or the driving gear of the machine itself must be so proportioned as to provide this reduction. The former is by no means an ideal arrangement, yet it is the only one now in vogue. The motor should be carried by the machine to which it supplies power, and all outside belts and gears should be discarded. To reach this perfected condition, we must either reduce the speed of the motor without increasing its size or lessening its power, or the machine must be so geared as to permit the use of the motor even at its present high speed. So far as the first requirements are concerned, electricians the country over are now studying the problem, and to say that they will not ultimately succeed would be presumptuous. The second question depends solely, we think, on the future demand created by the electric motor. If there should arise a market for a machine geared and adapted to be run by an electric motor, making say 1000 revolutions per minute, then the tool-builders would meet the demand quickly, and would introduce the necessary gearing. We do not think it probable that machine tool-builders will change their design to accommodate the motor simply for the sake of introducing a tool carrying in its own frame the device needed for driving it. In other words, tool-builders will not push the introduction of the motor, for the simple reason that they have nothing to gain by so doing. Their machines require just so much power to run them, and the source of that power, whether line-shafting or electricity, is in itself of no interest to them.

The user of the tools, because of the saving to be derived, will advocate the motor, and if this demand ever becomes of sufficiently widespread importance to justify it, then the builder will modify his tool to meet the requirements of the motor. He will do this by placing the motor on the tool, thereby doing away with the inconvenient, unsightly and power-consuming countershaft.

In order to accomplish this, it would be necessary in all cases to redesign driving gear, and in some instances to remodel the entire tool. At the present time we doubt if a line of electrically-driven machine tools would "take." The average mechanic has no leaning toward an excessively high speed power; he has become accustomed by long usage to a speed of from 100 to 120 revolutions. He will not take kindly to a tenfold increase. For this reason alone he would regard with suspicion a tool driven direct by a motor. It will therefore depend upon the user, whose pocket is most directly affected, to first employ the motor. The question is an exceedingly interesting one, and one that will compel close study and attention in the near future.

Progress in Steam Engineering.

In the year 1892, man has not made any special mark on the calendar of engineering progress. It has, however, says the *Age of Steel*, noted some extensive applications of what has been already reached by the engineer. The development along established lines has been large, and the utilization of what is already definitely usable has been kept to date in a loyal and practical fashion. The triple and the quadruple engines have made their way into large plants, where, as a rule, the bicomponent is, or has been, a favorite. In the rate of speed some of our railways have lowered their record, the New York Central running the Empire State Express on a regular schedule of 440 miles from New York to Buffalo in 504 minutes, while a compound high-speed passenger locomotive on the Central Railroad of New Jersey has broken all previous records by running a mile in 39¼ seconds.

The same advance has been made in speed in marine engineering, the transatlantic record being lowered to 5 days, 14 hours and 14 minutes by the Inman steamship, City of Paris. In river and coast shipping, the old-time paddle-wheel steamer is being replaced by the propeller, an innovation that is finding its way in the ferry traffic of New York and Boston. With better steam facilities in reach, the ship architect has constructed a Cunarder that from stem to stern will measure 700 feet, with others designed to outmeasure the latest giantess of the ocean by 100 feet. In the handling of engines and boilers there has been an increase in efficiency and a decrease in the usual tally of disasters and explosions. In some prominent electric works the countershaft is disappearing, and engines are being belted to the dynamos direct, or transmitting the moving parts of electrical machinery upon their main shafts.

In cable and electric street railways, improvements in methods are continuous, and in such huge undertakings as the World's Fair and the utilization of waterpower evolved in the tunnel at Niagara Falls, the science of steam engineering has added new triumphs to its practical record. With other enterprises now in contemplation, the future has its broad promise of greater things; and taken all in all, both in the manipulation of motive-power and the efficiency of its mechanical aids, the table of progress, if lacking in epoch-making changes, is by no means behind the duties and opportunities of 1892.

Test of the Wire Gun.

At the third shot fired from the Brown segmental tube wire-wound gun at Birdsboro, Pa., the enormous pressure of 60,000 pounds to the square inch in the powder chamber was registered by the United States Army pressure gauges used. This gun was fired for the first time, Dec. 3, at Birdsboro, Pa., where it was built. Although it is only a 5-inch rifle the projectile used at each of the three shots weighed 84 pounds. The standard navy 5-inch shell weighs only 60 pounds.

The gun was mounted on an old carriage, placed on a railroad flatcar and was fired into a stone quarry on a down grade. For the first shot a charge of ten pounds of sphere-hexagonal powder was used as a warming charge and no chamber pressure was taken.

For the second shot a powder charge of 15 pounds and an 84-pound shot were used. The chamber pressure was found to be 28,265 pounds per square inch.

On inserting the third 84-pound shot it was found to be rather a close fit. The shot was of cast iron, not finished with the nicety usual in service shells, and the gun itself was only rough bored. It had no lining tube whatever, either in chamber or in chase. It is probable that this shot, by reason of lack of finish, was a mere trifle too large for the bore and that thereby the friction was made so great as to cause exceptional pressure in the gas confined behind it. The powder charge was 18 pounds, and this ought to have given a chamber pressure of about 35,000 pounds per square inch. The recoil was excessive, the car running up the incline an unusual distance. The breech mechanism worked perfectly and there was no alteration whatever in the bore, but when the pressure gauges were examined they were found to register 60,000 pounds pressure per square inch.

As such a result would have burst any other kind of gun, Lieutenant G. N. Whistler, the ordnance expert in charge of the gun, was unwilling to make public the pressure obtained until he should make a further test. Having now done so and proven conclusively that the pressure of 60,000 pounds

was reached, Lieutenant Whistler has made a report to that effect.

The test means that a gun superior to any other gun heretofore known has passed through a crucial and unexpected trial with complete success. The standard guns of the army and navy are not fired with a maximum pressure of more than 38,000 pounds, and are not built to withstand more than 43,000 pounds per square inch.—American Manufacturer.

Scientific Progress.

The Reflector with the Projection Microscope.

The following interesting communication has been addressed by Mr. G. B. Buckton to *Nature*:

The lantern is now used for so many purposes—scientific, photographic, and recreative—than any improvement in its construction will be acceptable. When we look into this instrument whilst at work we must be disappointed at the large quantity of light lost by reflection and by dispersion—light which ought to go to the illumination of the screen. In the ordinary form of the lantern three lenses of dense glass are employed as condensers. Each of these six surfaces reflects and scatters the light, and the glass itself is absorbent of its rays.

The dioptric construction of the projection lantern has been well worked out by Messrs. Wright, Newton, Salomons, and others, but the catoptric principle, which would eliminate almost entirely these disadvantages, has been scarcely at all studied.

Although my experiments have been made solely with the limelight in various forms, the following remarks may equally apply to light given by the electric arc:

If a reflector be used, instead of the ordinary condensers, it is obvious that the position of the lime cylinder must be reversed. This will present no difficulty, for the tube holding the jet can be bent into a helical form. The dark image of the lime cylinder also will have no more practical disadvantage than is experienced by a like image formed by the small plane speculum of the Newtonian telescope.

As to the mirror itself, although a parabolic form is the most correct, a spherical surface will be sufficient for mere illuminating purposes, and thus expense may be spared in the grinding of the more difficult curve. A speculum of from 5 to 7 inches in diameter, having a radial curvature of from 2½ to 3 inches, will grasp a large quantity of light, much more than that obtainable from the 5-inch condenser usually employed.

Silver deposited by one of the various reducing processes on the surface of a clear glass lens will have many advantages over a metal mirror. The front surface will give perhaps the finest definition, but by silvering the back part of a spherical glass film, or that of a ground lens, the brilliant surface will remain untarnished for an indefinite time, and the whitish bloom formed by slow volatilization of the incandescent lime is easily removed. The silver film adheres with remarkable tenacity, and it will bear a great deal of heat without blistering or becoming detached.

I have had considerable success in constructing such mirrors from the large ornamental glass spheres blown in Germany, and silvered within by Liebig's process, viz., with milk sugar and ammonio nitrate of silver. A glass sphere of 10 or 11 inches in diameter may be easily cut into eight or nine mirrors by a red-hot iron, and this without distributing the silvering, which will require only gentle friction with a pad of cotton impregnated with a trifle of rouge to brighten it. Thus, at the cost of a few shillings, eight or more mirrors can be made, and also provision be made against possible accidents of cracking by heat.

The light-radiant is so placed that the secondary focus is intercepted by a plano-concave lens of dense glass, as has been happily proposed by Mr. L. Wright. The convergent rays from the speculum are thus made into a parallel beam, which must be deprived of its heat by an alum-trough, for the light and heat at the substage condenser is very great.

Convergence, I find, is usefully promoted by a plano-convex lens of about eight inches focus, placed two or three inches before the above-noted plano-concave lens. In all other respects the arrangements are like those of the usual modern projection microscope.

I have pretty constantly used the ether-oxygen saturator, and I consider it to be perfectly safe, if ordinary precautions be taken. The oxygen, compressed in cylinders, is much recommended, as there can be

no mixture of vapor, except at the right place. The U-shaped horizontal saturator, plugged with flannel, must be well charged with ether, or with the best gasoline, and care should be taken, before beginning or ending an exhibition, to shut off the oxygen tap before closing the ether tap. This will prevent the harmless "snap" from the mixture in the small chamber at the joining of the gas tubes. If a disc more than eight feet be required for the microscope, it will be well to use hydrogen gas instead of ether, since the caliber of the jet cannot in the ether light very well exceed 1¼ of an inch.

As an extra security, I pack the mixing chamber with asbestos-fibre, moistened with glycerine; but, as before urged, the oxygen must leave the saturator, saturated.

To insure the coincidence of the foci of the reflector with the optical axis of the microscope, it will be well to place three adjusting screws in a triangle behind the mirror, and this last may have both a small vertical and horizontal movement.

I claim for this catoptric arrangement a larger grasp of light than can be got from ordinary lenses, and this may be effected also at a small outlay. For the amateur constructor the plan will afford many advantages.

The Action of Alkalies on Glass.

The following facts concerning the action of solutions of alkalies and acids upon glass have been collected from the results obtained by F. Foerster and others who have experimented in this direction:

1. Solutions of caustic alkalies act upon glass much more strongly than water, since, except in very dilute solution, they dissolve all the constituents of the glass as such.
2. Of the caustic alkalies, the most active is caustic soda, then follows caustic potash, and then ammonia and baryta water.
3. Rise of temperature increases the action of the alkalies very considerably.
4. The action of the alkaline solution increases with the concentration at first rapidly, but afterward only very slowly.
5. Highly concentrated solutions at the ordinary temperature have less action than more dilute ones.
6. Pure alkaline solutions, not too highly concentrated, have less action upon glasses than such as have been rendered impure by small amounts of silicic acid.
7. Alkaline carbonates, even in very dilute solutions, attack glass much more strongly than water. Their mode of action corresponds rather with that of other salts than with that of the caustic alkalies. In equivalent concentration, solutions of sodium act more powerfully than those of potassium carbonate.
8. The action of salt solutions upon glass is made up in a manner which varies with the concentration and the kind of salt, of the action of the water itself, and that of the salt which is present.
9. Both these modes of attack are differently influenced by the composition of the glass.
10. Those salts act more strongly than water whose acids form insoluble lime salts. The action of these increases with concentration.

Metallic Chromium Obtained by an Electrolytic Process.

In a recent number of *Comptes Rendus* Mr. E. Placet describes a new electrolytic process by which he has succeeded in obtaining pure metallic chromium, which has formerly been but a laboratory curiosity, and in some cases was not pure chromium at all, but merely a more or less pure carburet of that metal.

To an aqueous solution of chrome-alum he adds an alkaline sulphate and a little sulphuric or other acid. In electrolyzing this solution beautifully brilliant deposits of pure chromium are formed on the negative electrode. Its properties are as follows: It is very hard, has a bluish-white color, resists atmospheric action, and is attacked only by concentrated nitric or sulphuric acid and concentrated solutions of potash. He said that this process may be applied on a commercial scale, which, if true, represents a very important step, as the alloys of chromium, notably those with iron and steel, are becoming of great importance.

He also states that he has succeeded in electroplating brass, bronze, copper and iron with desirable thickness of an adherent deposit of chromium resembling oxidized silver. At the time of reading his paper before the Académie he showed specimens of pure metallic chromium weighing over two pounds, and also samples of chromium alloys and brass ornaments electroplated with chromium.

Useful Information.

Electric Cars.

"Do you know why an electric-car goes uphill slowly, as though drawn by pony mules?" asked an electrician the other day, says the *St. Louis Republic*.

"There are some things I do not know," I responded, "and that's one of them."

"Well, I'll tell you," said he. "There is a certain amount of voltage or electro-motive force distributed over the line, and in order to keep each car running at a general average rate of speed, no car can be allowed to usurp more than its share of pressure. For instance, if one electric car should be thrown wide open and permitted to run uphill, it would for a minute reduce the time of every other car on the road. Hence the motormen have positive orders about slowing down at every pronounced rise in the roadbed."

"Another thing," continued the talkative electrician. "A great many people wonder why there are so many overhead wires along an electric road, and which of them are alive or dangerous. Ninety-nine persons out of a hundred know nothing about it. You have noticed that alongside the pavement on both sides of the street is strung a large, well-insulated wire, almost large enough to be a cable. That is the feeder. In other words, that wire carries the current from the power-house and at certain intervals contributes it to the trolley wire. It is well-nigh impossible for an accident to happen to the feeder, but there would have to be a direct ground connection before much damage could be done. If the feeder should break and fall to the ground, it would emit a blaze which would prove a warning to the passers-by."

"On either side of the trolley wire are two wires which seem to be useless. They are dead and are only intended to shield the trolley. Suppose these wires were not there and a telephone wire should fall across the trolley! Instantly the voltage which transmits the cars would be flashed into every telephone which had a connection, and the result would be a severe shock. As it is, falling wires of any kind are caught by the side wires, and hence never reach the trolley wire. There's your primer lesson in electricity. Some day I will tell you about amperes, volts and ohms."

Rectifying Petroleum.

A new process has been brought out recently by Messrs. Verschave and Barron, says the *American Manufacturer*, for the rectification of petroleum, which practically depends upon the action of the following mixture:

Water.....	10 parts
Liquid ammonia.....	20 "
Nitric acid of about 40° B.....	60 "
	100

This mixture, after being allowed to cool, is placed in a lead lined vessel in which previously about five pounds of finely ground stone, preferably that obtained from Lorraine, have been placed. Into this about 100 litres of distilled petroleum are turned and the whole agitated. It is then allowed to settle for eight to ten hours, the time depending upon the quality of the petroleum. The clear petroleum is then siphoned off, leaving the residue resulting from the treatment with the acid liquid at the bottom. The purification in this process depends upon the joint action of the acid mixture and the decomposition of the stone by the same. The treatment, in addition to removing impurities, removes to a large extent the characteristic odor of petroleum, while it is claimed to diminish its inflammability and increase its lighting power. The treated product is more limpid than ordinary oil, and possesses a faint yellow color.

SOUND is transmitted to the ear by the vibrations of the air. When one particle of air is made to vibrate, it sets the adjacent particles vibrating, and so a sound wave, if not obstructed, passes in all directions from the sounding body. The calculated velocity of sound in the air, when the temperature is at the freezing point, is 915.69 feet per second; but the experiments of Moll Vaubeek and Kuytenbrouwer, performed in 1823, over a distance of 57,839 feet, showed the velocity to be 1089.42 feet per second.

CHROMIUM.—Chromium is a metal, so-called from the numerous coloring compounds it produces. It was first discovered by Vauquelin, in 1797, since which time it has become an important accessory to the list of dyestuffs now in use in the ordinary coloring establishment. Chromium occurs naturally as chromate of lead and chromate

of iron. It is usually obtained in the form of powder or scales, but as a metal it possesses no practical value. The property which characterizes this substance as valuable in the textile world is the bichromate of potash obtained by heating the chrome-iron ore in powder with one-quarter of its own weight of nitre, and then digesting in water. The result of this mode is to dissolve out the chromate or potash, a yellowish salt, and when this material is acted upon by sulphuric acid, it is converted into bichromate of potash. This substance, which is soluble in water, and is extensively used by the dyer and calico printer, readily crystallizes in orange-red crystals.

English and American Locomotives.

An English engineer, writing to the *Engineer*, not long since, gave his experience with English and American locomotives. In explaining why, on a recent occasion, a Baldwin locomotive kept the track while an English engine ran off, he said: Greater flexibility of frames, bogies that follow with the greatest ease the sinuosity of rails, wider wheel-tread, explains, I think, everything clearly for the Baldwin engine. The particular class of engines alluded to by me, had under them bogies as stiff and rigid as the engine frames, central bearings as wide as the bogie frames, long, straight male centers, deep female centers with strong side springs, all this adding to the non-flexibility of bogies; add to this the fact that the bogie was between the engine main frames, the wheels of which rubbed against them on almost all curves, and I think you will see that, as a bogie, it was almost useless.

Often have I watched with painful interest the leading wheels of these bogies while rounding curves. The flanges were soon worn to a sharp edge, owing to the fearful grinding on the edges of the rails; the bosses of wheels soon made deep recesses in axle-boxes, cutting through the flanges of the brasses before they were worn at the crown. The trailing-tender bogies soon showed the same excessive wear on the tires of the leading wheels. This was caused by the weight of the tender being all on side-bearings. Running-tender first caused the wheels to jump the track, and soon great danger was incurred in going over the facing points. The bosses of the engine wheels—the wheels were inside the frames—soon wore deep recesses on the axle-boxes, owing to the rigidity of the frames; the platforms at the cylinder ends worked loose, and after one round trip of less than 200 miles—shed half-way—the engines came in rattling like old mowing machines.

Some Peculiar Effects of Electric Welding.

Some of the men employed at the Kolomna iron works, in Russia, have lately had some unpleasant experiences. Electric welding is practiced there according to the Bernados process. While engaged on the trying work the artificer's were, of course, protected by tinted glasses, but the skin being exposed, the following symptoms were manifested: Burning sensation on the skin and in the eyes; in from three to four hours, discharges from the nose and the eyes; three to four hours later, a dry cough; four to five hours later, swelling of the skin and development of other symptoms; eight to ten hours from the commencement of the disorder, continuous irritation of the eyes, lasting from four to six hours; and, finally, coloring of the skin. Then the various effects ceased, and the skin began to peel. On the third day the cuticle had completely decorticated, and by the sixth all the painful symptoms disappeared. But for weeks afterward the skin remained colored. These effects, it would seem, are exactly the same as those which are induced under scorching by the sun. The best protection which can be afforded the workmen against the evils mentioned, M. Maklahoff, the manager of the works, believes consists in a covering of yellow waxed cloth or red and green veils.—*Electric Review*.

MAGNETS AND THE HUMAN ORGANISM. Experiments have recently been carried out at the Edison laboratory by Dr. Fred Peterson and A. E. Kennelly to prove that no therapeutic effects result from the application of magnetism to the human system. It has been commonly supposed for some time that the magnetism of dynamos has some direct influence upon the bodies of animals, and these experiments were undertaken with a view to settle the question finally. For purpose of experiment the armature was taken from a dynamo, and in the cylinder formed by the inner ends of the set of powerful converging field magnets a dog was confined and kept for a period of five hours.

The intensity of these magnets was from 1000 to 2000 C.G.S. lines to the square centimetre. At the end of the time mentioned the dog was set at liberty, and beyond his apparent joy at thus being set loose the operation did not seem to affect him in the least. A boy was also confined for a short time in the same position, and was also uninfluenced. Several other experiments of like nature were made. Dr. Peterson and Mr. Kennelly conclude from their experiments that the human organism is in nowise affected by the most powerful magnets known to modern science.

PLENTY OF PLATINUM.—There is no fear of the sources of platinum failing to meet the demand; consumers have only to fear trade combinations or "rings." According to the *Journal of the Society of Arts*, there are strata at Bisserski, in the Ural mountains, which can alone supply the total quantity of platinum required for the consumption of the world for many years to come. Platinum is found in Brazil and in the Cordilleras, where it occurs in hard serpentine rocks; it is only in the deposits of the Ural mountains that the metal is found in grains. The richness of the sand in which these grains occur is represented by the figures 17 to 21 grammes of sand. Stories are told in the Urals that, when the demand for platinum was insignificant and the price very low, the goldminers who found this metal in grains while gold-seeking, used to use the grains for shot instead of lead for firing at wild birds. All the platinum extracted from the Ural mountains, after having paid a tax of 3 per cent in kind, is sent to St. Petersburg for treatment and shipment to foreign markets. Throughout the whole world only about 3000 to 4000 kilograms of platinum are annually used, but the consumption steadily increases.

NEW DISCOVERY

Mines Revived and Miners Enriched

By the wonderful MacArthur-Forrest Process, Controlled by the Gold and Silver Extraction Mining and Milling Co., E. A. W. Tabor, Pres.; Leonard Gow, V. Pres.; H. A. Jones, 2d V. Pres.; P. Geo. Gow, Technical Mgr. and Asst. Treas.; T. L. Wiswall, Gen'l Mgr. and Sec'y; PETER MCCOY, Treas.; W. L. Cooper, Eng.

TRADE MARK.

General Office of Company:
Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingstone Gold Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champ's Moes, Hunnig District, Yavapai County, Ariz.; The Crowned King and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Con. Gold Mining Co., Revenue via Norris, Mont.; and others in course of erection.

The object of this company is to introduce the Mac Arthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process. If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 60 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubes especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ores for this process is the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,
P. O. Box 926. Gen. Mgr and Secretary.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as oozes, hurdy-gurdies, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' lach, etc. A very practical work for goldminers and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

MINING AND SCIENTIFIC PRESS.
The Leading Mining Journal in America. Established 1860. Latest Discoveries in Science and Improvements in Mining and Mechanical Arts illustrated or described. A Standard Illustrated Weekly published at \$3 a year by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1890.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the why and wherefore. It contains 166 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, cloth, postage free. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 104 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

Electricity.

The End of the Lamp Case.

After several years of legal warfare the question of the absolute ownership of and right to manufacture incandescent lamps has been finally settled and the Edison interests have come out victorious. A decision in the case of the Edison Electric Light Company and the Edison General Electric Company, appellees, against the Sawyer-Man Electric Company, appellant, was handed down by the United States Circuit Court of Appeals on December 15, sustaining the injunction obtained by the Edison Company restraining the Sawyer-Man Company from making, using or vending the incandescent lamp patented by Edison, which has been the subject of the long legal contest. The decision, however, places some restrictions upon the successful parties which will, in a measure, protect those who will be directly affected by it. The court decides that the injunction order appealed from should be so modified as to cover only those lamps made in infringement of the second claim of the patent. It should also contain a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal on the part of the General Electric company to supply lamps on reasonable terms to the owners of electric-light plants which were installed before the Circuit court decided the validity of the patents. The date of this decision is July 14, 1891. Those concerns which manufactured lamps while the patent was in dispute, the court says, took a risk, and should their interests depreciate on account of being deprived of the use of the lamp, it is their loss, and they must suffer the consequences. The court also says that those who obtained their lamps from infringers are likewise infringers, but those who obtained them before the decision of the Circuit court sustaining the validity of the patent have much stronger equities than have the manufacturers and infringers. As to the legality of the combination known as the General Electric Company the court holds that whether it is legal or not the fact remains that the complainants hold the patent. It is now thought probable that the General Electric Company will at once proceed to stop the manufacture of lamps by those concerns which are now classed as infringers. The Westinghouse people, on the other hand, maintain that their new lamp will be entirely free from the Edison patent, and that the decision will not affect their plans as regards the World's Fair contract.—Electrical Age.

A Storage-Battery Experiment on Ninth Avenue.

An electric car equipped according to the system of the Acme Storage Battery Company of this city is now being operated experimentally on the tracks of the Ninth Avenue Street Railroad. This car weighs 6½ tons, and is provided with 144 cells, each weighing 27 pounds and having a capacity of 140 ampere hours at an average discharge rate of 25 amperes. The grades on the Ninth Avenue road, from 54th street to 116th street, a distance of three miles, are exceedingly heavy, one of them, at the end of the route, being no less than six per cent for a distance of more than 200 feet. On the up trip 31 amperes are usually consumed; a capacity of 75 amperes may be called upon at any time.

The time usually occupied on the up-trip is 24 minutes and 50 seconds. On the return trip, during which the grades are mostly descending, the average current drawn from the battery is 19 amperes, or little more than half of that required on the up-trip. The average time of the down-trip is about 22 minutes and 30 seconds. The entire trip both ways has been made in 47 minutes and 20 seconds. A specially designed motor, the company alleges, is one of the features of this system. The aim has been to make a cell which, while having the least weight for its storage capacity, shall at the same time be so constructed as to avoid the deteriorating influences which have usually caused the rapid destruction of storage cells employed in this class of work. The car made one trip last week when the tracks were in a wet and slushy condition. A fair speed was made and maintained on all the grades. The company manufacturing this system claim that they can run their cars at a cost of only nine cents a mile.

FROM calculations made of the amount of heat given out in a coal-burner and in an electric heater, Mr. P. K. Stern concludes that the former is seven times the latter; or,

in other words, it will take seven times as much coal to produce the same amount electrically as by means of the ordinary coal-burner. But allowing for the difference in price between the hard coal used in stoves and the soft coal in an electrical station, the cost is reduced to about two and one-third times the price of stove or furnace-heating. He points out the fact that in coal-heating there is necessarily a great waste, while in electrical-heating much greater economy can be exercised. This still further reduces the cost of electrical-heating. He mentions an electrical water-heater which is attached to an ordinary faucet in such a way that the cold water on passing through it instantly becomes heated to a temperature which may be regulated as desired. This avoids the use of large quantities of hot water being kept on hand, which naturally represents a vast deal of heat.

Continuous to Alternating Current Transformer.

A most interesting invention of Sir David Salomons and Mr. L. Pyke has for its design and object to change a continuous current of 100 volts and 10 amperes into an alternating current having an electromotive force of 100 volts and one ampere and an alternation rapidity of 1,000,000 per minute. This is ingeniously effected by means of a motor-driven alternator, says the London *Electrical Review*. Hitherto nothing has been accomplished within a tithe of 1,000,000 alternations. The diameter of the machine does not exceed one foot for the rotating portion, and as more than 10 poles to the inch could not well be obtained, the requisite alternation frequency is arrived at without an excessive speed by a simple and highly effective plan, viz, by rotating the field and armature of the motor in opposite directions, the brushes of the commutator proper being carried by the field.

The reactionary effect on the field is necessarily as great as the tendency of the alternator to turn, their speeds being equal, thus 3000 revolutions is equally divided between the two bearings.

The primary current is taken to and the alternating current is brought away from the rotation portion by carefully insulated wires passing through the spindles, which are hollow, being connected to their respective terminals by the device of rings and spindles.

As the whole of the weight is overhung, it is absolutely necessary that the bearings are true, and as the diameter of the polar faces is very small, necessitating very small air space, white metal thrust bearings are employed.

This apparatus will be of great value for the quantitative investigation of phenomena, as yet but crudely explained by means of inappreciable currents.

Sir David Salomons recently exhibited the alternator at the Institution of Electrical Engineers, together with a transformer for raising the potential of the alternating current to 100,000 volts.

Electrical Disinfecting.

Some weeks ago we referred in these columns to the possible advantages of using electrically ozonized air as a germicide, more especially in connection with cholera epidemics; but there are also other methods for preparing disinfectants by cheap electrical processes which may appeal to the public more directly, because instead of the refreshing ozonized air, they involve the use of liquids, which are malodorous, a quality which the public have unfortunately become accustomed to associate with all effective disinfectants to such an extent that now a disinfectant may almost be defined as something which smells worse than the odor of the other poisons in the air. The process which we refer to is that which has long been known as the Hermite process, in which a current of electricity is passed through a chloride solution developing in it hypochlorides, which are powerful disinfecting agents. This process has already been in use largely for bleaching paper, and is, therefore, nothing very new, but its recent introduction at Havre and Rouen, in France, for preparing disinfecting solutions to be used in connection with the cholera epidemics appears to be a new use. The installation required consists simply of a steam engine, a dynamo, the electrolytic bath and a pump. The ordinary sea-water is pumped through this bath and is collected in storage tanks. Unfortunately, no figures of the cost are at hand, but in a case which concerns the protection of a large country like this from the introduction of an epidemic of cholera, the expense, which would probably be small, in this case, ought to play no part whatsoever.—Electrical World.

AN ELECTRIC EXCAVATOR.—The first electric shovel in the United States has just been installed in the works of the Purington-Kimbrell Brick Company, at Purington, a suburb of Chicago. The clay here has previously been excavated by a steam shovel, the scoop being operated by an engine and boiler enclosed in a car, running on a temporary track. The change was made by replacing the steam engine and boiler in the car by a 50 h. p. Thomson-Houston motor, supplied with a current from a generating station several hundred feet away.

IN transmitting electric-power from Laufen to Frankfurt, 108 miles, the actual loss of energy was 18 to 20 per cent in the triple process of transforming a current of from 200 to 300 volts into a current of high intensity but small volume, transmitting this current over naked copper wires on ordinary telegraph poles, and finally transforming it again into a current of ordinary pressure.

THE following pretty experiment is suggested by Charles Wetterer in the *American Machinist*: If iron or steel filings be corroded in a damp atmosphere, and this rust added a little at a time to a jar of diluted sulphuric acid, the crystalline carbon particles that existed in the metal unite to form large crystals; these same will be of the hard diamond form.

Unitarian Literature

Sent free by the CHANNING AUXILIARY of the First Unitarian Church, cor. Geary and Franklin Sts., San Francisco. Address Miss S. A. Hobe, as above.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$3.00 post paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

TWENTY-SEVENTH INDUSTRIAL EXPOSITION

OF THE
MECHANICS' INSTITUTE
AND
PRELIMINARY WORLD'S FAIR EXHIBIT OF CALIFORNIA.
OPENS JANUARY 10, 1893.—CLOSES FEBRUARY 11, 1893.

NEW FEATURES! SPECIAL ATTRACTIONS!

Among which will be the ANNUAL EXHIBITION OF THE NORTHERN CALIFORNIA CITRUS FAIR ASSOCIATION, a grand display of natural products of various counties of the State, the largest collection ever seen in this city of valuable Stationary and Portable, an Orchestra of Fifty Musicians, including noted Soloists and Miss May Cook, the young California cornetist, six large Aquariums, Machinery in motion, objects of art, industry and manufacture.

ADMISSION

Adult's single admission in daytime, 25c; evening, 50c. Child's single admission, daytime, 15c; evening, 25c. Season tickets issued only to members of the Mechanics' Institute. Double season ticket, \$2.50; single season ticket, \$1.50. Season tickets may be obtained by non-members at the following rates: Double season \$5; single season, \$4, which includes membership in the Institute, subject to confirmation by the management and dues for the present quarter.

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to offer to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Professional.

A. LEOFRED,
Mining Engineer,
Graduate of Laval & McGill.

Head Office, QUEBEC. Branch Office, SHERBROOKE.
Branch office, MONTREAL, 17, Place d'Armes Hill.

STEPHEN H. EMMENS,
Consulting Engineer and Chemist,
Youngwood, Westmorland County, Pa.
SPECIALTIES: Nickel, Tin, Dry Placer Development, Treatment of Refractory Ores, Electric Heating and Smelting.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering,
Surveying, Architecture, Drawing and Assaying,
728 MARKET ST., SAN FRANCISCO, CAL.
Open all year.
A. VAN DER NAALDEN, President.
Assaying of Ores, \$25; Bullion and Chlorination Assay, \$25; Blowpipe Assay, \$10. Full Course of Assaying, \$50. ESTABLISHED 1864. Send for Circular.

The Evans Assay Office and Chemical Laboratory.

628 MONTGOMERY ST., San Francisco.
ROOMS 46 and 47 MONTGOMERY BLOCK.
Ore Assays, Analyses of Minerals, Waters, etc., made. Lessore given in Assaying and Chemistry.
W. N. JEHU, Manager.

EVERETTE'S MINING OFFICE.

(Pioneer Mining Geologist's Office of the Pacific Northwest.)

Mining Law, Mine Examinations, Metallurgy.

ASSAYING AND ANALYSIS.
"Consulting Associate Mining Attorney at Law."
Will examine and report upon "Title and Exact Value" of GOLD, SILVER, LEAD, COPPER, COAL, IRON, CLAY or other MINERAL PROPERTIES in any part of the world. Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.

MINING MACHINERY

VULCAN WIRE ROPEWAY,

for Conveying ORE, CORDWOOD, ETC.

SNYDER MINE, CAL.

In reply to your inquiry as to how the Tramways are doing, am prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

We can easily transport 65 tons of ore in 10 hours, with two men to load and one to tend brake, and with all the Wood Carriers on, we can transport 14 cords of wood in the same time.

When I look back upon the time when I was paying at the rate of \$2.50 per ton for hauling ore, whereas it is now done at the rate of 12c. per ton, making a saving of \$150 per day, and also, where it formerly cost me \$5.50 per cord for wood delivered at mill, it now costs me but \$3 per cord, making a saving of \$2.50 per cord—I must say that I feel pretty well over my Tramway investment for it is a PERFECT SUCCESS.

JAMES BARRON, Supt.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Cal veras Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no mere wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the edges and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flange when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

HURLETON MINES.—Oroville *Mercury*, Jan. 9: A rich strike is reported in the Pactolian mine at Hurleton. This mine was recently purchased by a local company, and a force of men placed at work developing the ledge. A tunnel was started in the hill below the first development shaft, and on Saturday, after mining a distance of 50 feet, the ledge was encountered. At the point of contact the ore is marvelously rich, fairly bristling with free gold, besides containing an enormous amount of sulphurets that assays very high. The owners are jubilant and will at once increase the working force. The ledge is from six to eight feet wide, and a mill will undoubtedly be erected. Geo. S. Coleman, superintendent of the Phoenix Mining Co., has a large force of men erecting a mill upon the property. It will be completed in a few weeks and commence crushing ore. The mining prospects in that section never looked brighter.

Napa.

THE MAGNESITE MINE.—St. Helena *Star*, Jan. 6: F. Sievers, of Chiles valley, appeared before the Board of Supervisors Wednesday morning and made the following statement, which we clip from the *Register*, regarding a much-needed highway: "W. P. Bartlett employs at the magnesite mine in Chiles valley in summer, six months, 13 men, in winter, six months, nine men, none of whom get less than \$2 per day, which is an aggregate in summer of \$650, and in winter \$450 per month at least. The hauling at present covers 15 tons daily. This, at \$2 per ton, makes an expenditure of \$30 daily, or \$750 per month. In the six summer months the furnace consumes 25 cords of wood every day, or \$300 per month. All these expenses, aggregating \$1600, are for wages, hauling and wood. This money remains in the hands of the Napa people. Besides this, the teamsters, having about 20 horses, buy all the feed for their stock in the county. The condition of the road over which this business must be done is, and always has been, very miserable. Now it is impassable. Mr. B. has to deliver, under contract, a certain quantity, and if not able to do so from the mines in Chiles valley, he will be forced to abandon the same and go to another county, where the owner of a magnesite mine has made him an offer to work, thus causing a loss of an income of \$1600 average per month to many residents of Chiles valley and Ruthersford. To avoid such a loss, Mr. Sievers proposes to have what he terms the 'cattle trail' between the old mill and the mine, called by courtesy county road," changed for a county road in the valley." The matter was referred to Supervisor Graves, who will lose no time in seeing what can be done to keep so important an interest as the magnesite mine moving in this county.

Nevada.

OSBORN HILL.—Grass Valley *Telegraph*, Jan. 7: The Osborn Hill mine has been bonded by parties in Grass Valley, and in a short time active operations will begin upon the property. The Osborn Hill is considered by mining men who are familiar with the property as one of the best mining prospects in this part of the country. It is admirably located, and in the early days considerable work was done on the mine. Considerable money has been taken from the mine, and a large ledge is there. Active work on the claim will soon begin, and it will make times lively around Union Hill.

Plumas.

RICH STAKE.—*Bulletin*, Jan. 7: From C. R. Thompson we learn that a rich strike was made at the Shenandoah mine last week. From a pocket about \$1000 has been taken already. The vein is about four feet wide and prospects well all through. The ledge is about 100 feet lower than the Mather tunnel and crosses the ravine 200 feet below the falls. It is incased by walls of slate and porphyry. About 25 tons of good-milling ore are on the dump, more hands have been put to work, and the company expects to put up the mill soon.

Shasta.

MINING OUTLOOK.—*Shasta Courier*, Jan. 7: The mining outlook for this vicinity is very good. We understand that several properties will be operated on an extensive scale, and outside capital will take a hand in their development. The dull boom of halting shakes the hills in all directions and the country is full of quartz prospectors, pocket hunters and placer miners, and enterprising owners of small mines are developing their property, for capital is looking for gold-producing mines these days. Muletown mountain promises to be the scene of a big mining boom in the near future. The Parker mine is showing some very rich ore, and a number of other good ledges are being opened. We are in a position to know that big and substantial developments will be made on that hill before many months. Mrs. G. R. Knox of Shasta, and J. Kahny and Aaron Bell of Redding, own a promising location on Muletown mountain, upon which assessment work is being done. Wm. Kellner has got out a lot of good rock, ready to run through his arrastre, near Middletown. The Lost Confidence at Iron mountain is turning out the silver bars, despite the bad weather. The works have run longer this year than usual, as they generally shut down before Christmas. We understand that the Minnesota mill, on Spring creek, which uses the Parmelee process, will start up soon, as they have a lot of good ore out. Mining matters are quiet at South Fork, but indications point to lively times in the

spring. E. L. Ballou is pushing work on his plant. South Fork has got some splendid ore, and all that the camp needs is less "wind-work," and more mining men like Mr. Ballou. That placer and pocket-mining is having a sort of old-fashioned boom in these Shasta diggings, is shown by the shipments of gold dust from this place of late. The men at the Hidden Treasure, on Iron mountain, struck the ledge last week. A 60-foot tunnel will be run in on the ledge and if it continues to hold out as rich as at present, a 10-stamp mill will be erected. The ore is very rich, and an extra force has been put on, making over a dozen men now at work. Grant Schroter intends to begin work on the Schroter mine, near the hospital. They will run a new tunnel on the ledge, and calculate to have the mill running in a couple of months. Farmer has purchased A. Leivisay's interest in the Leivisay and Brewer mine, adjoining the Pacific, owned by Crum and Farmer. Wm. E. Crum and his partner, Farmer, struck a rich pocket in the Pacific mine, about a mile northeast of Shasta, a few days ago, and panned out about 10 ounces of gold in half a day and have good prospects in sight. Crum took out \$250 in this mine some time ago, and "experts" pronounced the ground worked out. Farmer thought a little different, and went to work with Crum, and they soon came to the pocket. The mine is on Rock creek, a short distance below the road-crossing, and the owners, who are practical miners, are confident of striking it "heap rich." A 4-foot ledge has been struck in the New Year mine, near Hogtown, owned by Lorenz Garrecht of this place. Work will soon be commenced on an adjoining location, owned by Garrecht. Both promise to develop into valuable mines. Drury and Paige started up their arrastre this week. The mine is on Middle creek, just outside of town, and is owned by Eli and Oliver Drury, and Jim and Harry Paige. The mine is an old one, but the present owners have discovered that there is something in it too valuable to let it lie idle and will work it in earnest. Panfuls of dirt taken from any part of the mine show excellent prospects. They have a 200-foot tunnel showing a ledge from one to four feet wide. They calculate to run about four tons, averaging \$12 a ton, through the arrastre daily.

Siskiyou.

BLUE GRAVEL.—Yreka *Journal*, Jan. 11: Lee, Lash & Co., of the Greenhorn Blue Gravel mine, have shut down operations for the present, or until a new pump is procured to drain the claim. The water can be easily handled with a good pump, as they have a first-class steam engine to work one successfully. The company has a large extent of ground to work, ranging from 50 to 100 feet to bedrock, the gold being principally found in the blue gravel within 4 to 6 feet of bedrock. The *Ashtand Tidings* says: G. W. Crowson, who was over on Klamath river the first of the week, reports that the Pierson Brothers, of Lane county, have just started their new 4-stamp mill on their claim near the old Anderson ferry, Siskiyou county. One of the Piersons picked up a little piece of float rock on the claim of Crowson & Hills which was rich enough to rate at about \$16,000 a ton. They would like to find the spot where it broke loose from the solid quartz. The *Tidings* also says: L. W. Wright, of Hornbrook, was in Ashland last week, from whom it was learned that a very rich prospect has been struck by himself and a Mr. Cuthbert at a place about two miles from Henley, near C. B. Jilson's house. Those two gentlemen and C. H. Veghte, of Ashland, are interested in the claim, which will be a valuable property, if a ledge is found as the surface prospects indicate. Work was resumed again last week at the Spencer quartz mine, near Coles, just this side of the Oregon line, but the weather is becoming quite cool to cause another suspension, as the water supply is probably frozen again in consequence of the cold temperature of that high altitude.

Tulare.

GYPSUM.—Visalia *Delta*, Jan. 7: Messrs. Marcus Lavelle, Ewell Gilliam and W. F. Hall are interested in a gypsum mine in the Coast Range mountains, and they are selling immense quantities of the plaster for neutralizing the effects of alkali in our soil. The crude gypsum is mined and hauled to Coalinga, where it is ground up in a mill having a capacity of 2500 pounds per hour. The land plaster is very efficacious in its use on alkaline soil, and renders it rich. The gypsum is sown broadcast over alkali spots and then turned under the soil by a plow. The proprietors of the mine have orders for all the gypsum they can mine.

Tuolumne.

RICH DIGGINGS.—Tuolumne *Independent*, Jan. 7: Ed. Ogden discovered rich diggings, on Wednesday last, back of George J. Morgan's house, Matelot gulch, Columbia. Several school children were prospecting there, and Ogden asked them to let him try a pan. In the first pan he obtained nearly \$4 in gold, in the second \$8 and in the third about \$100, making a total of \$130. Some excitement was created and claims in that section are very desirable property.

NEVADA.

Washoe District.

CON. CALIFORNIA AND VIRGINIA.—Virginia *Enterprise*, Jan. 9: 1500 level.—The old east crosscut from the south drift, 30 feet south from the shaft station, has been extended 10 feet; total length reopened, 60 feet. A drain has been placed at the mouth of this crosscut, and water let in through a pipe in the dam is now running along the crosscut to the old slope timbers. The main south drift has been reopened to the sill-floor slope, and we are now closing the winze connection with the 1650 level by filling with waste rock to shut off the heated air and gas which come up from that

level. After doing some necessary work at this point, we will be prepared to resume the work of extracting ore from these stopes. There has been a gradual decrease during the week of gas escaping through the Con. Va. shaft. 1600 level.—Are repairing the main south drift and the east crosscut leading therefrom to the upraise connection with the 1500 level, north drift. 1650 level.—Have continued making necessary repairs to the drifts on the sill floors of this level. Have extracted from the old stopes, eight floors up in the upraise No. 6 carried up from the main northwest drift, and raised to the surface 44 tons of ore; average car assay value, \$30.19 per ton.

OPHIA.—1465 level.—The upraise started on the sill floor, on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground, 101 feet below the sill floor of this level, has been carried up 14 feet; total height, 66 feet, continuing in porphyry showing lines of quartz.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 18 feet; total length, 443 feet; continuing in a porphyry and clay showing lines of quartz.

OCCIDENTAL.—The main north drift, 750 level, has been extended 17 feet; face in low-grade ore. Have been cutting out a station in south drift, 750 level, where winze No. 2 was started near the foot of the upraise. Crosscut No. 2 from Zaidig drift, Suro tunnel level, has been advanced 17 feet; total length, 120 feet. The face is in porphyry and quartz.

BEST & BELCHER.—200 level.—During the past week the northwest drift has been advanced 13 feet through porphyry; total length, 135 feet. 900 level.—West crosscut No. 3 from top of upraise from 100 level has been extended 19 feet through hard porphyry; total length, 49 feet.

GOLD & CURRY.—200 level.—West crosscut No. 5, started 435 feet from main west drift, has been advanced 14 feet during the past week, passing through hard porphyry; total length, 228 feet. West crosscut No. 6 from main north drift has been extended 8 feet; total length, 61 feet; face in quartz and porphyry. On the Suro tunnel level, the joint north drift with Savage Co. has been advanced 18 feet during the past week; total length, 792 feet; face in hard porphyry.

ANNAS.—On the 420 level are retimbering and repairing main north drift. No work has been done in face of north drift run from east crosscut No. 1, north, during the week.

HALE & NOBACROSS.—We continue retimbering main shaft above the 700 level. Main Incline.—Are making the necessary repairs, and are retimbering incline above the 1800 level. 1800 level.—During the week west crosscut No. 1, 80 feet south of the incline was started and advanced 10 feet; face in porphyry. No. 3 west crosscut, north of incline was advanced 13 feet; total length, 218 feet; face porphyry. No. 4 west crosscut, north of incline, was advanced 18 feet; total length, 74 feet; face all in quartz.

EAST BEST & BELOHER AND NORTH GOLD & CURRY.—Drifting is being continued, passing through quartz that looks well.

UTAH.—340 level.—West crosscut No. 3 from the north drift from west crosscut No. 2, at a point 195 feet in from its mouth has been extended 20 feet; total length 64 feet. The face is in quartzite formation, showing clay separations and some water.

NEW YORK.—The west crosscut, 55 feet north of shaft, 850 level, is out 71 feet; face in quartz showing spots of ore, but as a whole of low grade. Shipped to Washoe mill the past week 173 tons 385 pounds of ore; milled during the week 173 tons 385 pounds of ore; on hand at mill, 60 tons; average battery assays, \$31.72; average car sample assays, \$32.74. Shipped to Carson Mint 425 pounds of crude bullion.

WADE SHAFT.—Joint west crosscut on the north line of Alpha, 1800 level, is out 190 feet; face in porphyry. The west crosscut from the northwest drift 300 feet south of the north line of Bullion, 1800 level, is out 155 feet; face in quartz yielding low assays. Heretofore we have been running the blower by means of compressed air, which has been expensive. We are now putting in a water-column in the Ward shaft to enable us to run the blower by a Pelton wheel.

CHOLLAR.—The north drift from the south line, 550 level, is out 75 feet; the face continues in quartz which gives fair assays. Two compartments in the main shaft have been retimbered for 70 feet above the 930 level. The north drift from the east crosscut, 160 feet south of north line, 930 level, is out 71 feet, following a clay wall, on the west side of which there are bunches of quartz, which yield fair assays.

BULLION.—East crosscut, 160 feet north of top of upraise, from east crosscut 320 feet south of north line, 1300 level, is out 26 feet; the face is in quartz and porphyry. The West crosscut from the northwest drift, 300 feet south of north line, 1800 level of Ward shaft, is out 155 feet; face in quartz yielding low assays.

UNION CON.—The joint Sierra Nevada and Union east drift, 900 level, has been advanced 26 feet; total distance west of shaft, 2795 feet; face in porphyry and small seams of clay, from which there is a strong flow of water.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 30 feet; total distance, 536 feet; face in soft porphyry with stringers of quartz and clay. The joint Sierra Nevada and Union west drift, 900 level, was advanced 26 feet; total distance west of shaft 2795 feet; face in porphyry and small seams of clay, from which there is a strong flow of water.

EXCHEQUER.—The joint Alpha and Exchequer east crosscut on north line of Alpha, 1800 level of the Ward shaft, is out 190 feet; face in porphyry. Heretofore we have been running the blower with compressed air, which has been expensive. We are now putting in a water-column in the Ward shaft, to enable us to run the blower with a Pelton wheel.

ALPHA.—The joint Alpha and Exchequer east crosscut, on north line of Alpha, 1800 level of Ward shaft, is out 190 feet; face in porphyry. Heretofore we have been running the blower with compressed air, which has been expensive. We are now putting in a water-column in the Ward shaft, to enable us to run the blower with a Pelton wheel.

SILVER HILL.—The southeast drift has been advanced during the past week 6 feet; total length, 21 feet; the face is in hard porphyry.

POTOSI.—The east crosscut from Potosi winze station, 100 level, has been connected with the west crosscut from top of raise from the 1100 level, giving us good ventilation. A drift was started from the southeast corner of the raise, which is now out 3 feet; face in porphyry. Extracted and sent to the mill the past week 316 tons 1500 pounds of ore from the 550, 930 and 1150 levels. Milled during the week 300 tons; on hand at mill, 88 tons 1150 pounds. Average battery assays, \$25.40. Average car sample assays, \$31.10. Shipped to Carson Mint, 538 pounds of crude bullion.

Pioche District.

NEW COMPANY.—Pioche *Record*, Jan. 7: The certificate of incorporation of the Polaris Mining Company was filed in the county clerk's office this week. F. P. Swindler, Wm. Lloyd and Geo. C. Blanchard Jr. are the incorporators. Working the Poorman group of mines just east of town will form part of the company's immediate operations, and other workings are contemplated in the near future.

Comet District.

GOOD VALUE IN GOLD.—Pioche *Record*, Jan. 7: Messrs. Schaefer, Cohn and Schumann are much pleased over the developments made in their Comet district claim during the past two weeks. They have opened up a mass of ore of unknown dimensions, and are still developing it. The assays vary, but a good portion of the find is shipping ore, and a carload will be sorted out and shipped within two weeks. The high value in gold which the ore carries makes the matter interesting. Comet district created much excitement here a few years ago, it will be remembered, and much work was done there; but the ore developed was mostly low-grade. Numbers of the claims are still maintained, but this new find is down the mountain-side in the low foothills, easy of access, and promises to develop into an immense property.

Yellow Pine District.

CLAIMS AND PROSPECTS.—Pioche *Record*, Jan. 7: The Grundy group, a massive lead property, lies 3½ miles west of the Springs. The ore is a most desirable quality for smelting, being carbonate of lead in lime (calc spar) and practically free from silica. The vein here also is a fissure in limestone. The group comprises the Grundy and the Maybel claims. On the Grundy the ore vein is from one to five feet wide, and a 100-foot shaft is sunk, exposing 50 feet of ore running 15 per cent lead and 25 ounces silver to the ton, while 50 tons are out on the dump. On the Maybel claim ore is developed for 100 feet in veins running from 4 to 15 feet in width. This ore runs 15 per cent lead and carries 35 ounces silver to the ton, and 100 tons are ready for shipment. These two claims are estimated to yield 50 tons a day. The Hunter group of three claims, the Hunter No. 1, 2 and 3, comes next, situated nine miles west of the Springs. The ore vein averages 10 feet in width, and though no development work has been done, ore is exposed and ready to mine for 200 feet on the surface, which will average 40 per cent lead and 35 ounces silver to the ton. Twenty-five tons a day is the estimated output here. Two other good locations, the Shansandoa Nos. 1 and 2, are situated 9½ miles west of the springs, in a vein similar to the Hunter group; ore a carbonate and galena, with a lime and iron gangue. Twenty tons are out ready for shipment, and the estimated output of the claim is 25 tons a day. Just east of these, and nine miles from the Springs, lies the Old Timer claim, where workings go down but six feet, while 20 feet of ore is exposed. It is a bed-vein, conforming to the limestone strata, carrying galena ore which averages 40 per cent lead and 30 ounces silver to the ton. Fifteen tons are out ready for shipment. Fifteen miles northwest of the Springs lies the famous old Potosi lead mine, where the Mormons and Indians in early times are said to have run out lead for the manufacture of bullets. The mine is patented and has lain idle for years. The ledge varies in width from 1½ to 12 feet, and has been worked to a depth of 125 feet in one or two places. An average of 40 per cent lead and 25 ounces in silver to the ton is found in the ore, though the surface workings are said to have been nearly pure lead, easy to mine and run into pure metal. About 100 tons of ore are extracted here and 10 tons a day can be relied on from the mine if worked steadily. Three miles southwest of the Springs lies the Columbia copper claim. Ten tons a day can be extracted on present developments, which run to a depth of but 15 feet. In the Maud claim, 9½ miles southwest of Good Springs, a lead deposit is found varying in width from 1 to 16 feet and over. It is a fissure in limestone, the ore a carbonate of lead, with a calc-spar gangue. Fifty feet of ore is exposed in surface workings which are but five feet deep. The ore runs 40 per cent lead and 12 ounces silver, and the claim can be relied on to furnish five tons a day for shipment. The latest reported discovery is the Singer claim, also a lead property, situated

about 8½ miles southwest of the Springs, and it is a promising piece of property. The vein here, like several of the others, is a fissure in limestone, with galena and carbonate of lead ore which will average 60 per cent in lead and 27 ounces in silver to the ton. The surface is scratched in several places, but not deeper than five feet, yet 100 feet of ore is exposed and 15 tons a day can be mined for shipment. This completes a brief review of over 35 ore-producing prospects in Yellow Pine district, showing by something more than mere general assertions what inducements of a mineral character exists in that section of our county to warrant the construction of a line of railway to develop it. Nearly all the claims mentioned are practically undeveloped, yet the extensive showing on the surface justifies the assertion that a year's work, with a railroad's help, will make Yellow Pine district the heaviest lead-producing section of the continent. Work is soon to commence on the 30 miles of road projected north from Goff station on the A. & P. road, and there is little doubt that the work will continue right on 60 miles farther to Yellow Pine. The country is said to be one easy to build over, and everything points to a belief that the whole 90 miles will be in operation by the latter part of next spring.

ARIZONA.

MOHAVE NOTES.—*Miner*, Jan. 9: Eugene Desty has made a number of valuable discoveries in the mountains west of the river. George Dougherty is working on his mine near the Nighthawk and is taking out considerable ore. A large number of new locations were made the first of the year and many old claims were relocated. Work on the Distaff mine is progressing finely. A larger force of men will be put on as soon as possible. Fifty tons of ore from the Gold Bug mine, Weaver district, were received at the Needles mill Friday for reduction. Rouse and Ferraris have a big body of ore opened up in their lease on the Nighthawk mine and are stopping out large quantities. James Dundon and Ike Hunt have a nice body of good ore in the Nighthawk mine, which they are taking out and preparing for shipment. J. W. Munn has a splendid showing in his Lucky Boy mine, in Music mountain. Considerable rich ore is being taken out and prepared for shipment. A number of mines in Aubrey district are showing up in good shape. With a small amount of work a large quantity of high-grade ore has been uncovered in a number of places in the district. The mill in Todd Basin will be started up in about two weeks, Frank O'Dea having leased both mill and Golconda mine. Mr. O'Dea is a first-class millman and will probably make a success of this venture. J. H. Cofer and S. S. Watson returned Monday afternoon from a prospecting trip in Wallapai mountains. They had the regulation prospector's outfit—several horses—and we understand they made a number of locations. Judge Murphy has just had the assessment work on a number of his claims near Cerbat completed. The ledges are large veins, carrying a high percentage of lead, and run from 20 to 30 dollars in gold and silver per ton. Work continues uninterruptedly on the Blake mine, southwest of Kingman. Some fine ore has been struck in the drifts, while a considerable body averaging an ounce in gold has been uncovered. The mine is destined to be a remarkably good property. The gold fields in and around Cerbat, reported in a recent issue of the *Denver News*, are no myth, but a reality. There is gold there, and in paying quantities, should water be got onto the ground. Many of the small ravines show up well in coarse gold. The mines of White Hills are now being worked in a systematic manner. Shafts are being sunk, whims erected, and everything is kept moving steadily along. We expect that as soon as water can be reached in the mines a new era in mining in that camp will be inaugurated. A Denver, Colorado, mining man visited the Eagle and Golden Eagle mines in Weaver district. He says they are immense properties, and with the right method of working will pay handsomely. The property is now owned by Messrs. Monaghan and Murphy, of Needles, and Henry Brown, of Weaver.

BRITISH COLUMBIA.

MINING DEVELOPMENT IN WEST KOOTENAY.—*Nelson Miner*, Jan. 2: The report which E. D. Ingalls, Dominion Inspector of Mines, will shortly present to the Government, will contain interesting information concerning our district. Among other things, a list of the shipping mines is given, and it is stated that the Mountain Chief and Mountain Boomer will also ship ore shortly. The amount of ore shipped to date is estimated at 160 tons, while 40 to 45 tons are being brought down to Kalso weekly, but are not sent on to the smelters as the navigation companies will not guarantee delivery. The correct spelling of the name of the mine which is known as the Rico or Reko appears to be Ruecau. With regard to work done more in our own immediate vicinity, not so much has been heard of it during the past year, as, owing to excitement about the Slocan, the Lardo, Crawford's Bay and other places, attention has been drawn away from the mines on Toad mountain, but still it is satisfactory to know that their owners have faith enough in their properties to stay with them. As to Toad mountain mines: A considerable amount of work has been done on the Silver King. Even if one knew how much, the penalty for divulging the secret (at present) is death, so that it is advisable to keep dark on the subject. On the Dandy, a 400-foot tunnel has been driven, tapping the ledge 120 feet from the surface. A level has been run on the ledge from this tunnel for 200 feet. The assessment work done on the western end of the Inqnois exposed a very large ledge carrying gray copper yielding high assays. Last year's work on the Grizzly Bear was continued and shafts sunk to tap the vein. On the Silver King, also, a shaft has been sunk

on the vein. The Hidden Treasure has had the assessment work only done on it, while the Last Chance, Jim Crow and many others show fair average veins, carrying copper and silver in paying quantities. On Esle Creek, the Poor-man group and others: About 150 tons of ore have been taken from these mines and put through a 10 stamp mill. Results show \$25 to \$30 per ton in free gold and a large percentage in sulphates. Between the Cottonwood Gold Mining Company's property and the Silver King group some very good showings have been discovered, giving assay returns of 40 per cent copper and \$30 gold to the ton. On Hall creek a strong ledge of gold-bearing quartz has been discovered, giving returns of \$10 to \$30 per ton. The placer mining on Hall creek has paid from \$5 to \$10 per day per man, and on Salmon river present indications are that a considerable amount of work will be done there next year. On Rover creek, a shaft has been sunk 20 feet on the upper tunnel of the Whitewater, and a crosscut has been driven 18 feet in the lower tunnel to tap the main ledge. On the Snow Water, a tunnel has been driven 35 feet to tap the vein. Two men will be working there all winter.

COLORADO.

THE PRODUCT OF THE SMELTERS.—*Georgetown Courier*, Jan. 7: The following is the grand totals of the smelters of the Colorado product of gold, silver, lead and copper:

Omaha & Grant.....	\$ 8,641,422 28
Omaha & Grant, Omaha.....	2,406,184 87
Boston & Colorado.....	3,477,198 00
Globe Smelting & Refining Co.....	4,188,315 16
Philadelphia S. & R. Co.....	4,903,302 35
Harrison Red'n Works.....	1,133,003 98
Arkansas Valley.....	1,737,577 52
San Juan.....	1,539,703 33
Colorado S. & R. Co.....	2,137,643 11
American Smelter.....	2,374,625 02
Pueblo S. & R. Co.....	3,627,077 49
Elgin Smelter.....	483,608 97

Holden, Leadville.....	100,230 76
U. S. Mint.....	1,120,075 04
Kansas City S. & R. Co. (estimate).....	200,000 00

Colorado product 1892.....\$39,445,641 92

INAHOS SPRINGS NOTES.—*News*, Jan. 7: Messrs. Owen and Oxley have made a very rich strike in their Silver Queen. The Santa Fe shipped upward of 40 tons of ore to the Silver Age mill this week. Egan & Orme report a big strike in Warren gulch. This discovery joins the famous Frontier mine. The Beecher mine in Virginia canyon is being worked by leasers, and is a steady producer of high-grade ore. The Lexington mine is being steadily worked under the management of J. E. Haman. This mine has paid its regular monthly dividends for some time. The Gem and Gem Extension mines are shipping daily several tons of smelting ore. These mines, if consolidated, would make one of the finest enterprises in this end of the county. The Arizona mine is being extensively developed under the management of Dr. J. I. Thomas. This mine has been a heavy producer of high ore in the past, and it will not be long until it will be paying. A. Abbott of Denver, general manager of the Orphan Boy Extension M. & M. Co., was here this week in the interest of that company, which is operating very extensively on Yankee Hill. The Bismarck and Solid Muldoon mines, operated by the same pool, are promising to become paying properties. The location is a most desirable one, being joined on the northwest by the Newton, General Thomas and Mattie mines. The General Thomas, operated by Allen Bros., is a steady producer of free-milling and smelting ore. This property, although having lain idle for many years, is now a bonanza, and the lucky operators will be rewarded with a handsome fortune.

IDAHO.

WILLOW CREEK MINES.—*Cor. Idaho Statesman*, Jan. 7: Dr. Calloway, of Caldwell, has just returned from the Willow creek mines, 20 miles northeast of Caldwell, full of enthusiasm over the prospect there. Some of the ledges, the doctor says, are simply immense, and the top rock runs, in some cases, as high as \$500 gold and silver to the ton. What is better, many of these improve as they are worked. On one of the ledges the top rock assayed \$6 to the ton, and at the depth of 20 feet the assays showed \$43 gold and silver, and apparently thousands of tons of ore within easy reach. The doctor has been in many mining regions in different parts of the country, and says, without hesitation, that he never saw a better outlook for high-paying mines than exists at Willow creek. It is the pretty general opinion here among mining men that a great future is in store for the region in question.

MONTANA.

THE ANACONDA.—*Butte Inter-Mountain*, Jan. 7: The Anaconda and St. Lawrence mines employ a small army of men yet, though no ore is being hoisted from their depths. Around these properties every day may be seen over 120 men engaged in unloading timber, cutting it into shape for the mine and piling up lagging. The timber is arriving every day, the most of it being red fir from Washington and Oregon. The mine will be in splendid shape when work is resumed. At the smelter it is stated that there is ore enough on hand to last for nearly three months, but it is expected that the retimbering of the shafts of the different properties will be completed before that date.

THE MISSOULA.—Two weeks ago the Butte & Boston Company took charge of the Missoula mine and in future will work the property. It is understood that Messrs. Persons and McGovern, who held a lease on the ground for about eight months, cleaned up a snug sum from the ore stopped out above the 100-foot

level. At present a number of miners are employed in developing the shaft to the 200-foot level, from which point crosscutting will begin. The property adjoining the Missoula, which is also Butte & Boston ground, and which is under lease to Dower, Morgan & Co., is yielding some very rich ore.

THE WILD BILL.—The Wild Bill mine, situated near the Grey Rock and owned by the Kleinschmidt Brothers, Lee W. Foster and others, was leased this week to Messrs. Wiseman, Mitchell and Youton. It is understood that the lessees will at once begin work on the property by the sinking of the shaft an additional 100 feet, as soon as the new hoisting works are erected.

THE BOSTON.—During the past week great preparations have been made for the further development of the shaft at the Boston mine, a property bonded last spring by the Alice Company. For several months a force of about 24 men has been employed in development work. Recently a very rich body of ore was uncovered and Superintendent Hall decided to work the property on a larger scale. The machinery in place was much too small for any extended operations, and the hoist being rather cramped a change became imperative. Accordingly, an engine capable of sinking to the 700-foot level was placed on the property this week, a new 50-horsepower boiler was also placed in position and a new hoisting works erected. The improvements will all be completed early next week, when the work of sinking will be commenced.

THE PURITAN.—Perhaps the largest and certainly the richest body of ore yet unmined in the Puritan was struck at a distance of 230 feet in the east drift last Monday, says the *Phillipsburg Mail*. The vein was found on the foot wall and has rapidly widened from the thickness of a knife blade until now it measures over 14 inches of solid galena, carrying large quantities of native silver. The walls in the face of the east drift are 16 feet apart, and the formation is such as warrants the continuance and enlargement of the ore body above described. All the present indications point to the early resumption of all operations on a larger scale than was at first supposed the company would ever attain.

NEW MEXICO.

NO MINERS WANTED.—*Silver City Enterprise*, Jan. 7: A false impression has gone forth that miners are in great demand in this camp (Mogollon). The impression is misleading, as there are miners here in sufficient number to supply the present demand. Those coming here in search of work, unless engaged before starting, do so at their own risk, and it is to be hoped that this warning, given in a friendly spirit, will be accepted in the same spirit in which it is tendered.

THE MOGOLLONE.—The mines are working satisfactorily and the output for the present year will attract the attention of capitalists to this long neglected section. The Mand S. mill is kept running without interruption. The Last Chance leasers have been bothered somewhat by their water-supply pipes freezing up, thus interrupting millwork, greatly to their pecuniary loss. It is to be hoped, however, that with continued good weather their troubles may be ended for the season. It is reported here, and currently believed, that the Little Fannie mine will start up very shortly, and possibly one or two other mines in this locality.

OREGON.

A VERY RICH MINE.—*Statesman*, Jan. 7: The Patton mine, of which a great deal is heard just now, is located two and a half miles from the Southern Pacific depot at Ashland. A five-stamp mill is running there now. A clean-up was made last Tuesday from a run of 24 days, 202 tons of ore having been put through, and the yield was 426 ounces of gold, with a mint value of \$6390. There was a previous clean-up of a ten days' run, and the result was \$3340. The mine was discovered about a year ago by the Patton brothers. Sheriff Kelly, of Portland, is the president of the company owning and operating the mine, and he bids fair to be transformed into a full-fledged millionaire. Some of the oldest miners are greatly excited over the wonderful and almost unprecedented yield, and they say the prospect for one of the richest mines ever discovered is right indeed. The farther they go the bigger and better is the lead. If such a yield should be reported away up in some mountain, where men could not climb, nothing could prevent hundreds of people from rushing thither; but, almost on the line of a railroad, this thing excites only a passing remark, except from the overenthusiastic and excitable.

SOUTH DAKOTA.

ORGANIZED FOR BUSINESS.—*Deadwood Pioneer*, Jan. 6: A company of well known Plattsburgh, Neb., gentlemen have bought in on the properties of Josiah Craig, in the Richmond Hill section, and propose to develop on an extensive scale what they believe to be a valuable group of claims. The group comprises 16 claims, lying about 2000 feet south of the Iron Hill. In the lot, good ore has been found on two claims, while a plat of some 20 acres of hill ground has a blanket covering of from 1 to 12 feet in thickness of decomposed rock which runs from \$3 to \$5 to the ton. The first move of the new company will be to build a tramway to Coal creek, about half a mile distant, and work this blanket formation. This work will begin early in the spring, and as soon as it is well under way, a shaft, 5x10 feet, will be sunk on what is supposed to be the main ore body. Two shafts of this size have already been sunk to a depth of 30 feet, and both gave very satisfactory returns. This and other development represents the work of four men from early in November. The gentlemen who have bought in on this promising property are C. H. Parmele and son, Charles Parmele, S. H.

Atwood, G. M. Craig and Judge Newell, all of Plattsburgh. The senior Mr. Parmele, as is generally known, is at the head of the Cass County and other banks; and in this same connection might be noted the expectations of certain well informed Spearfish people, that the same gentleman will establish a bank in that city in the near future. The gentlemen who represent the above company are careful investors, and have sufficient capital to carry out their ideas of mining. Mr. Parmele, Sr., has had extensive practical mining experience in other States, particularly in California.

UTAH.

THE ONTARIO.—*Park Record*, Jan. 9: A few weeks ago the *Record* published an article to the effect that the Ontario Company was considering the feasibility of increasing its facilities, and that Mr. Chambers was then absent in the East to consult with the controlling stockholders. It now seems that the meeting resulted in a decision to build a new and much larger mill than the one now in operation, and it is generally understood that the work of construction will commence as soon as the preliminaries can be arranged. The mill will be built on the hill above the mouth of the old drain tunnel a few hundred feet below the present mill, the site having been surveyed last fall. It will be much larger than the present structure, and will be equipped with the Russell leaching process. The first use the plant will be put to will be to leach the old Nos. 1 and 2 tailings dams, both of which contain silver in paying quantities. After this work is completed, the mill will be put to work on Ontario ore and no more shipments will be made. The *Record* has been informed that the company has decided that a saving can be made by milling its own base ores, as the freight and smelting charges amount to considerably more than the value of the lead which makes the ore base. It has been demonstrated that the lead can be destroyed and the ore leached at a great saving to the company, and as cheap reduction is a great item, the Ontario has decided to make a fair test of reducing its base ores. It is calculated that by the time the mill is constructed and the old tailings dams worked up, that the drain tunnel will be completed and the mine freed of water, which in itself will be a big item in favor of the company's sinking fund, and will be the means of instilling new life and energy into the Park's richest and heaviest producer. Coupled with this proposed improvement, should silver advance to \$1 or over, Park City will witness a forward movement such as the most sanguine never dreamed of, and in the estimation of the writer the construction of this new mill is the first glimmer of light from an approaching dawn that will shine with increasing brightness as the years pass along.

DALY NO. 2 SHAFT.—The Daly No. 2 shaft is 1107 feet deep and is said to be one of the finest pieces of work in the West. The timbering is particularly fine and is as smooth as the walls of a parlor. A drift has been run south 200 feet, and as yet very little water has been encountered. The big pump ordered some time ago for this shaft, is expected to arrive every day and will be placed in position as soon as possible. The pump station, 25x12 feet, has been cut and the steam piping is being wrapped with asbestos, and everything placed in readiness to get the machine in operation on short notice after its arrival. A buckboard has also been placed in the pump shaft and works to a charm. The Daly No. 2 shaft is a complete piece of work and a monument to the skill of the mechanics who constructed it.

Wanted, A Partner

With capital sufficient to develop a gold mine in Shasta county, California. The property is located in the gold belt from which a large amount of gold is being extracted. The mine is showing well so far as work is done, being from 8 to 12 inches in rich ore. The company owns a mill and water rights, with U. S. patent. Plenty of fine timber on the ground. This is an exceptional opportunity for capital. Address, "SHASTA," this office.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Gallego on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISELL, 650 Market street, Chronicle Building, San Francisco.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco: **PACIFIC GAS COMPRESSING Co.** Object, to manufacture all kinds of gases made from chemicals or any substance used for aerating liquids of all kinds and for dental, medical and other purposes. Directors—W. P. Redington, San Francisco; G. W. Fletcher, Berkeley; F. W. Marvin, San Francisco; L. J. Cowgill, San Francisco, and E. J. Calley, Oakland.

PACIFIC GROVE, MONTEREY AND DEL MONTE RAILWAY. Object, to obtain franchises for and the construction of a street railroad from the city of Pacific Grove to Monterey. Directors—J. T. McCresson, H. N. Bryant, A. Barvard, Montfort W. Bell, William H. Chapman, George W. Hopkins and Nathan C. Carnall.

Market Reports.

Financial and Commercial Review.

SAN FRANCISCO, Jan. 12, 1893.

Mexican Silver Trade.

The imports of silver from Mexico at this port, principally by rail, for the quarter ending December 31st compare as follows:

Dollars.....	\$2,673,344	\$3,760,723
Bullion.....	87,935	111,904

Total.....\$2,761,279 \$3,872,627
The receipts for the last quarter were the largest ever reported, despite the unprecedentedly low price of silver, showing that the metal has not yet fallen to the cost of production in Mexico. The receipts for the past two calendar years compare as follows:

Dollars.....	\$6,409,680	\$9,683,351
Bullion.....	267,988	366,492

Total.....\$6,677,668 \$10,049,843
The receipts last year are unparalleled. The shipments of Mexican dollars hence to China and Japan in 1892 were \$10,582,286.

SILVER—The same stagnant conditions rule as for some time past. There was a slight advance in yesterday's quotations over the rates for the week, but it was not material. Delegates from the late monetary conference at Brussels are beginning to return to the United States, and are busy explaining how it was done, or, rather, how it was not done. There is some feeling of expectancy as to next spring's meeting of the conference, and, in many quarters, a genuine belief is prevalent that much good may ensue. They think that the world will by that time have discovered that America considers this a serious and even vital question. At any rate, the recess of the conference is much better than adjournment.

METALS—It is very difficult to discover any new features in any of the metals. At this season of year, transactions are slow and very little is to be noted. Quotations are unchanged from last week.

San Francisco Metal and Coal Market.

Mining Share Market.

There have been some advances in prices of stocks during the week, and on several days the market was comparatively active. There is no news of very special interest from the leading properties, unless it was from Potosi, of which several thousand shares changed hands this week. During December there were worked at the Nevada mill 1672 tons of Potosi ore. The gross proceeds in bullion were \$31,866.26, and the cost of reducing the same \$10,935.79. The average assay value of the ore per ton was \$24.42, the gross average per ton \$19.06 and the net average per ton \$13.06. The mill worked the ore up to 78 per cent.

Edward Cahill, one of the oldest members of the San Francisco Stock and Exchange Board, who recently gave up his seat to his nephew, Edward F. Cahill, on account of illness, died in this city Tuesday morning.

At the annual election of officers of the San Francisco Stock Exchange, the old board of officers were elected, consisting of A. F. Coffin, president; W. Edwards, vice-president; Fred W. Hadley, secretary; George T. Marye, treasurer; and O. V. Walker, caller.

At the annual meeting of the Pacific Stock Exchange the following officers were elected for the term: President, R. G. Horn; vice-president, S. Ows; secretary, J. Frank Moroney; treasurer, M. Goldman; caller, J. B. Bourne; executive committee—William Bannan, I. Herzberg, C. Hirschfeld.

At the annual meeting of the stockholders of the Silver King Mining Company 37,370 shares were represented and the following officers elected for the

ensuing year: Thomas B. Pehy, president; George C. Hickox, vice-president, and F. A. Berlin, M. A. Jackson and W. A. Jones, directors. J. W. Pew was reelected secretary, and Bank of California treasurer. The secretary's financial statement shows a credit of \$122,327.

At the annual meeting of the Argenta Mining Company Thomas Cole was elected president; J. L. Brown vice president and R. R. Grayson, William Bowers and H. H. Todd directors. R. R. Grayson was elected secretary and G. V. Grayson treasurer.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

The following brief list by telegraph, for Jan. 10, will appear more complete on receipt of mail advices:

Sidney F. Baker, Santa Barbara, combination index device; John T. Bibb, Tacoma, buggy; James T. Bibb, Tacoma, buggy; Frank C. Bieri, San Francisco, bolting and conveying machinery; James E. Chapman, San Jose, border for walks, etc.; Edward C. Emde, Tacoma, steady device for portable engines; Benjamin Holt, Stockton, traction engine; Robert D. Hume, Gold Beach, Or., can-lacquering machine; George Johnston, San Francisco, ore concentrator; Charles B. Kendall, San Francisco, and H. Schake, Baltimore, can-seaming machine; Joseph Kraker, San Francisco, filter; Frank B. Long, Los Angeles, key touch adjuster for pianofortes; William Mann and George Johnson, Los Angeles, butter mold; Newton C. Miller, French Corral, Cal., hydraulic milking apparatus; Charles M. Prever, San Francisco, elevator hatchway attachment; Samuel Rogers, San Francisco, detonating compound; George M. Williams, Santa Rosa, printer's cabinet.

Notes.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AUXILIARY STEERING GEAR.—Herbert I. Wetzel, Oakland, No. 488,746. Dated Dec. 27, 1892. This invention is designed to provide an auxiliary steering gear, which may be instantly put into use in case the main rudder or steering gear is disabled, but which at all other times is out of the way. In the run just above the keel and below the propeller-shaft (that is, in the "dead wood") is made an opening which extends entirely through from side to side, and is of sufficient size to receive a rudder. The thickness of the keel at this point is considerable, and the rudder may be equally thick. The forward portion of the opening has a vertical concave groove in which the front end of the auxiliary rudder fits on pintles, serving to enclose the front edge of the rudder and also limit the amount of its turn in either direction. Ring bolts are fixed in the rear sides of this auxiliary rudder and chains attached, these chains then being led through the counter of the vessel to the deck, where they may be attached to the regular steering chains when necessary. If any accident happens to the main rudder the auxiliary one may be put into use. At all other times it is held firmly in the central position by the steering chains and suitable shackles. The apparatus may be used either temporarily while repairs are being made to the main apparatus, or, if found necessary, it will be found sufficient to guide and control the steamer until she can reach port, where repairs can be completed.

BILLIARD TABLE.—Allen F. Scott and John W. Wright, S. F. No. 488,743. Dated Dec. 27, 1892. This improvement in billiard tables consists in a novel construction of elastic cushions, adjustable corner-supports and attachments

therefor, and intermediate reinforce cushions along the rails. The invention is more especially designed for small, movable tables, which can be used in rooms not large enough for ordinary billiard tables. The table may be, however, of any suitable size. The cushions consist of an endless elastic tube or solid cylindrical band, which is preferably made of elastic rubber. This patent covers, among other things, reinforces, arranged at intervals between the hands and table, and against which the bands are supported. These supplemental supports are designed to support the hands and increase their elastic force between the angles of the table.

CAR COUPLING.—Frank M. Ryan, S. F. No. 488,718. Dated Dec. 27, 1892. It consists of jaws pivoted transversely to the line of travel of the cars so as to swing in a horizontal plane and having recesses formed in their meeting edges for the reception of the head of the draw-pin. In conjunction with these are weighted or spring-actuated levers pivoted to swing in vertical planes having upwardly projecting hooks or lugs which engage the shanks of the draw-pin, holding levers to lock them in position when the coupling is complete and to unlock and open them when the coupling is to be broken. In conjunction with these levers is a mechanism by which they may be actuated.

BATTER-CAKE MIXER AND DEPOSITOR.—Edward Stempel, Alameda, No. 488,721. Dated Dec. 27, 1892. The invention relates to the general class of Kitchen utensils and particularly to a utensil the object of which is to provide a vessel in which the batter may be mixed and from which it may be evenly deposited upon the griddle to form any number of cakes. The batter is mixed in the vessel, and when the griddle is hot the vessel is placed on the stove over the griddle. A valve-rod is operated, which opens a number of apertures in the bottom of the vessel, and the batter flows out evenly and is distributed in a suitable number of cakes over the surface of the griddle. The valve is then closed and the vessel removed from the stove to await the next operation.

WATER-WHEEL.—Clark Taber, Sumpter, Oregon. No. 488,723. Dated Dec. 23, 1892. The invention relates to that class of water-wheels in which the wheel operates within an encircling casing having a fixed abutment, said wheel being provided with radially reciprocating hockets adapted by their withdrawal to pass the abutment and by their projection to form the necessary water chamber in the casing. The patent covers a certain novel construction and arrangement of parts.

BOOKS ON ASSAYING.

BY C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes where he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Lignite; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 310 12mo. pages, with illustrations well bound in cloth; 1892. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—JUST OUT.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is reprinted by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Restraining the Debris in the Rivers.

At the Drainage and Reclamation Convention which met at Sacramento this week, it was announced that the convention was held for the purpose of hearing facts, plans and propositions, and for the further purpose of determining practical methods and providing ways and means for the relief or permanent reclamation of the overflowed land of the Sacramento valley, and for averting the danger threatened by the annual floods of the Sacramento river and its tributaries. David M. Lubin of Sacramento was elected chairman, and in the course of his introductory remarks expressed the opinion that it was not advisable at this time to antagonize the miners. The farmers might need the miners in their present struggle for drainage and reclamation.

That was a very sensible observation, because if the two classes "stand in" together they can accomplish something, while by antagonizing each other, the whole object is endangered. Senator Ford, of Sierra Co., will introduce shortly a bill providing that the State expend \$250,000 toward the construction of debris dams above the head of navigation in the rivers, to prevent the debris which has accumulated coming farther down. This money is only to be spent in case the U. S. Government appropriates at least an equal amount for the same object. Now, to this reasonable proposition the valley men should agree. They should lay aside their prejudice against debris dams and help themselves and the miners by getting something done. The Caminetti bill now pending in Congress, while it appropriates nothing at present, provides that appropriations may be made for this purpose, and if the State will aid, both the agriculturists and miners will receive the benefit, and the rivers will be improved.

It is not intended to build dams for any particular mines or groups of mines, but to build at such points above the head of navigation of the Sacramento and San Joaquin rivers, and on the main tributaries or branches, or places adjacent, such works as will effect the object of keeping back the material now, or hereafter to be lodged in the tributaries of these river systems, from injuring the navigable rivers. There would have to be both a Government and State Commission, each in control of the respective funds, but empowered to act together. This would provide a practical remedy, and both factions should aid in the passage of the measure when it is presented to the legislature.

MEN who were intending to go to the San Juan placers in the spring, and were not quite sure where their outfit was coming from, can now rest content. If the latest reports are true the whole thing was a fake.

GEOGRAPHICAL SOCIETY OF THE PACIFIC—Lieut. Commander Z. L. Tanner, U. S. Navy, commanding the U. S. S. Albatross, will deliver a lecture on Monday, Jan. 23d, before the Geographical Society of the Pacific, Union Square Hall, 421 Post St., on the subject of "Cable Surveys from California to the Hawaiian Islands." An invitation to attend is extended by the Society to merchants and others interested in the building of a submarine cable-line between San Francisco and the countries bordering on the Pacific. The rooms of the Geographical Society of the Pacific are in the Mercantile Library building, corner Van Ness and Golden Gate avenues, and are open daily from 9 A. M. to 5 P. M. for the convenience of members who wish to consult its files and maps. The latest bulletins of sister societies throughout the world are

The Anti-Debris Association.

Why the new association should call itself the "State" Anti-Debris Association when it only represents half a dozen counties is not quite clear, but that is what it has been named. The executive committee had a meeting on Monday and several new members were added, to take the places of those whose terms of office had expired. The newly admitted members consist of J. M. Morrison and Thomas Jenkins of Sacramento county, W. F. Hoke and T. B. Hull of Sutter county, H. Kraft and G. G. Kimball of Tehama county, and J. A. Saul and E. Casselman of Yolo county. The committee proceeded to elect officers for the ensuing year, and J. M. Morrison, chairman of the Board of Supervisors of Sacramento county, was elected chairman of the committee, and Robert Cosner, Sheriff of Colusa county, was re-elected secretary. E. Greer, whose term of office had expired as a Sacramento supervisor, was elected a member of the executive committee. The other officers will be elected next month. Mr. Wilbur, the manager, desiring to retire his successor will be chosen. For the ensuing year the following finance and auditing committee was appointed: L. P. Farmer, John C. White, Robert Cosner, Thomas Jenkins, H. Kraft and Edward Fagan. For the purpose of properly presenting to the legislature such measures as may be desired for the benefit of the people of the valley, and of opposing such measures as

PLACER COUNTY'S TRIUMPHAL ARCH AT THE MECHANICS' INSTITUTE FAIR.—See page 35.

kept on file. All information at the disposal of the society will be cheerfully given by the assistant secretary, Mr. Thos. F. Trenor. This society was organized in 1881. The president is Prof. George Davidson, and John Parttridge is secretary.

ON Tuesday the McGarrahan quicksilver mine bill was taken up in the U. S. Senate, and an argument in support of it was made by Wilson of Iowa. After some debate the Senate refused to pass the bill over the President's veto by the necessary two-thirds vote. The vote was—ayes 29, noes 18. The bill thus received its death blow for the session.

THE total output of copper by the Old Dominion Copper Co., A. T., during the year 1892, was 8,019,059 pounds, to produce which 34,269 tons of ore and 8,340 tons of lime were used in smelting. The largest production of any previous year was 7,720,015 pounds in 1890.

A CLEAN-UP, amounting to \$118,000, has been received from the Utica mine, belonging to Hayward and the Hohart estate.

THE working force in the Con. Cal. & Va. mine was increased on Saturday last by the addition of 12 men.

may lead to a resumption of hydraulic mining, the following legislative committee was appointed: Hon. William Johnston, Hon. F. R. Dray, Hon. A. H. Rose, John C. White, E. Greer, George Ohleyer, Robert T. Devlin, Edward Fagan, Thomas Jenkins, Hon. J. C. Snowhall, W. H. Garnett and W. P. Craig. The manager reported several cases of violations of injunction, and confessed that his information showed him that Chinamen were the ones who did the greater portion of the illicit mining now being done.

COLONEL D. H. JACKSON, superintendent of the Holmes mine, has returned here from Candelaria. Owing to the prospect of a continued shut-down of the mine because of the low price of silver, Colonel Jackson has called his resignation to the London syndicate who control the property, but has as yet received no reply.

RUTHERFORD B. HAYES, ex-President of the United States, died on Tuesday at his home in Fremont, Ohio, where he had resided since the conclusion of his Presidential term.

THE Standard Consolidated Mining Company of Bodie district has received a bullion shipment, valued at \$17,662.02, representing the December product of the mine.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Placer County's Triumphal Arch at the Mechanics' Institute Fair, 33.
 EDITORIALS.—Restraining the Debris in the Rivers; The Anti-Debris Association; Miscellaneous, 33. Comment; The State Mining Bureau, 34. Citrus Fruits from Mining Counties, 35.
 MISCELLANEOUS.—Coast Industrial Notes, 35. Product of the Precious Metals in 1892, 36. The Local Coal Trade; Carson Valley Rancher, 42.
 CORRESPONDENCE.—Tiru Mining District; The MacArthur-Forrest Process, 36. How Ore is Purchased, 37.
 MECHANICAL PROGRESS.—Silencing Gas and Steam Engine Exhausts; Wide or Narrow Tires: A Trade Necessity, 38.
 SCIENTIFIC PROGRESS.—Dr. Gilbert on Evolution of the Moon; Converting Heat into Work; Electricity and Gas, 33.
 USEFUL INFORMATION.—A Change for the Better; Repairing a Broken Steamship Shaft; Miscellaneous, 39.
 ELECTRICITY.—Use of Accumulators; An Unsolved Problem; Electrical Railway Mail Tube; The Alternating Current Ampere, 40.
 MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings, Assessments, Dividends, Etc., 47.
 MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific States and Territories, 45-46.

Comment.

For this fiscal year ending June 30th, 1892, there passed through the Custom House at this port 3,104,789 pounds of silver ore. During the same period the amount of duty collected on lead in ores was \$6,964.17. Most of these came from Mexico and Central America countries. The shipments from these sources are increasing quite rapidly, much of what was formerly sent to Great Britain or Germany now coming here. Aside from the benefit to the local smelters the increase of ore shipments to this port is of decided advantage to our merchants and manufacturers, since the owners are apt to make then their purchases at the point where the bullion is obtained. The machinery and mine supplies are sent back from here on the vessels which bring the ores up, so the new trade is of great advantage to San Francisco in every way.

This new Mayor of San Francisco in refusing to sign an authorization of payment for bituminous pavement because it was not done according to specifications has done a good thing, and practically served a notice on contractors that they must do good work or quit. In his veto he says: "This work has not been done according to specifications in the judgment of the Superintendent of Streets. This being the case, it precludes any action looking to payment until the work is done to the satisfaction of the Superintendent of Streets and the board. The only procedure by which contractors have a right to receive payment had better be established at once, and all persons engaged in the contracting business be informed by your action that specifications must be strictly complied with to entitle them to payment." We have always been rather unlucky in this city in the matter of our street pavements, notwithstanding the immense sums spent upon them. This has been mainly due no doubt to careless and inefficient work. In giving up cobbles and basalt blocks, and taking to bituminous rock and asphalt for paving the citizens confidently looked forward to great improvement in the streets. But in many cases good material improperly laid has made people lose faith in bituminous rock. This is a question which interests the mining community, since the bituminous and asphalt deposits of this State are the sources from which the adopted paving material are derived. Properly mixed and laid on a good foundation, a noiseless, clean and durable pavement is produced. But with poor foundations and scant quantity, it cracks and breaks and needs constant repair. The property owners have to pay the full prices for good work according to specifications, but half the time get poor work done. It looks now as if the new Mayor, Superintendent of Streets, and Supervisors

were going to take vigorous action, and compel the contractors to do the work on the streets as it should be done. The Mayor's first veto is a good sign, and it is to be hoped that this will not be a mere spasm of virtue, but establishes a precedent which will be continued.

The Anti-Debris Association has appointed a Legislative Committee to "present to the legislature such measures as may be desired for the benefit of the valley people, and oppose such measures as lead to a resumption of hydraulic mining." It would have been perhaps more polite to have said: "to oppose such measures as may lead to a resumption of hydraulic mining where it does any harm to the streams or adjacent lands." But they qualify it not at all and oppose all hydraulic mining on general principles. The association has also decided to present a memorial to the legislature, giving the present status of hydraulic mining and expressing the objects of the State Anti-Debris Association pending any contemplated legislation. In view of the fact that Congress is dealing with the subject, and that United States courts have decided that hydraulic mining may go on under certain conditions, it is not quite clear that the legislators will see any way to interfere in the matter, even if it wanted to. However, the anti-debris people prefer keeping up the fight for fear that the miners, having gained the point of a favorable Federal court decision, and called the attention of Congress to their condition, may be still further benefited unless there is active opposition.

In all the monstrous scandal occasioned by the Panama canal exposures in Paris, where it has been shown that most of the money has been spent in bribery and corruption, it is pleasant to note that none of the engineering fraternity are implicated. De Lesseps himself was a great promoter, not great engineer. Engineer Fisch of the Comptoir Iron Works testified that the canal company was struggling constantly against the most outrageous demands by contractors. Despite the opinions of expert engineers, the company usually yielded to these demands. This is the only time the engineers have been mentioned as far as we have noticed, and the mention is favorable. It shows that they remonstrated at exactions and overcharges, but that the company went its own way and disregarded their advice. Many persons sent down as engineers were not really of the profession, and doubtless they were put at such places as the contractors desired, as the whole thing was a monstrous swindle from beginning to end. But no engineer of name or distinction has been mentioned as having received bribes, which is greatly to the credit of the profession.

GOLD miners interested in the cyanide process for beneficiation of ores should carefully read and digest Mr. Paul's article on the subject, which appears in another column. This gentleman has had abundant practical experience in all the various details, and from the fund of information thus gained draws freely for the benefit of his fellow-miners. What he says about the methods employed and difficulties overcome will throw much light on the subject. All this should be of decided benefit to the many now experimenting or working with the process. The MINING AND SCIENTIFIC PRESS has devoted much space to consideration of the MacArthur-Forrest process with a view of bringing prominently before the mining public both its merits and demerits. There has been a free discussion and expression of opinion on the part of its friends and those it has disappointed. The opinions of Mr. Paul are entitled to special respect in view of his extended experience; and, while it may be confessed that he is interested in the success of the process in Shasta county at least, it is the belief of all who know him that he is honestly seeking light and endeavoring to perfect a practical working process which may be applied economically to the sulphuretted ores of California.

At a meeting of the executive committee of the State Miners Association on Wednesday the proposed amendments to the original Caminetti bill were discussed. The word "must" inserted by Senator Felton, in place of the word "may" by Mr. Caminetti, compels all miners, whether they already have restraining works or not, to come under the supervision of the U. S. Engineers, and to relinquish their rights to them. The penal clause inserted at the request of C. P. Berry, of the Anti-Debris Association, includes even those mines which are now working without doing damage. As at present amended the bill is objectionable to the miners. At the meeting on Wednesday it was decided to send a representative to Washington to secure, if possible, an amendment to the penal clause to make it apply only to works which do damage to the rivers and which are interdicted by the courts. Niles Searles, of Nevada, was unanimously chosen to go to Washington. John Hays Hammond was elected alternate in the event of Judge Searles' inability to go. A penal

clause was to be expected on the bill, but as at present drawn it works a hardship on the hydraulic mines which have been permitted to work by the U. S. courts. The recent State miners convention objected to Senator Felton's insertion of the word "must" in the bill, and the matter was explained to him. Notwithstanding this, however, he had the objectionable word introduced. The bill is therefore not at all to the liking of the miners, and not what their convention or executive committee indorsed.

Stephen M. White, of Los Angeles, will represent California in the United States Senate in place of C. N. Felton, having been elected by the Legislature on Wednesday last. Burke, the Nonpartisan from San Francisco, and Kerns, the Populist from Los Angeles, voted with the Democrats for White, and thus with the absence of the Republican, McGowan of San Francisco, gave the requisite number to elect. Mr. White was born in this State, and has long been identified with the Democratic party, of which he is one of the foremost orators. In his speech to the members of the legislature after his election he had the following to say on the mining question: "I trust that I may to some extent aid in the passage of that character of legislation which will enable the mining industry of our State to be prosecuted under such circumstances as to avoid interference with agricultural pursuits and so as not to obstruct the free navigation and use of our streams. If mining can under this limitation be carried on (and it appears possible that it can be) it is unnecessary to point out the benefits that will accrue to all from this renewed activity and vitalization of an almost abandoned industry. Our resources cannot be too varied, and we should be loth to abandon any legitimate means afforded by a generous Providence for our advancement." This sounds very broad and very well, and Mr. White must be taken at his word. Nevertheless it will be well for the hydraulic miners of this State to get what favorable legislation they can during this session of Congress. We seem to have some indistinct recollection of years ago, when Senator White was a member of the legislature, and they were discussing debris dams. There was a talk of five per cent. tax, and somebody, to prevent a favorable measure passing, moved to amend by making the tax on gross proceeds 25 per cent., which was practically prohibitory on the mines. Mr. White voted for the 25 per cent. amendment. He may, however, like others, have since experienced a change of heart, but then he may not have done so.

The State Mining Bureau.

A correspondent of one of the daily papers, writing from Sacramento with reference to the probable abolition of the railroad and forestry commissions, says there will be a move also to abolish the State Mining Bureau as a State institution not wanted by either the miners or farmers. The latter class should have nothing to say of the matter one way or another, as they know nothing of it; but the miners of the State are entitled to some consideration, and, as a class, they will seriously object to the abolition of this institution. Mining has done a great deal for this State, but the State has done very little for mining. The Mining Bureau is the only institution maintained by the State for the benefit of the mining industry, and it should be continued without curtailment of any of its features.

This talk arises from the comments of the Governor in his message, relating to the cost of printing of the State Mineralogist's report and the plan upon which the Bureau should be conducted. He recommends that the Trustees be given greater power, and that they select the employees. All the suggestions of the Governor should of course be given due consideration, since he intends them evidently for the improvement of the institution, but he in no way even hints at abolishing the Bureau.

There are doubtless many ways in which the State Mining Bureau could be improved, and it will be well for all interested in it to suggest needed improvements rather than encourage any idea of its abolition, simply because it has not fulfilled all requirements. The reports have been voluminous but discursive. Much which has appeared could have been spared; and much that was wanted has been given no place. But all this could easily be remedied were not the political features given undue prominence. That is to say, with a view of obtaining county and individual influence in the matter of appropriations during legislative sessions, a great mass of matter has been printed which could have been condensed into much smaller compass had this incentive been wanting.

The legislature has insisted on fieldwork and resolved that a specified proportion of the funds should be spent in this direction. This was done owing to a tendency to employ a number of men in the office duties without any special beneficial results that could be noticed. But there is room for useful office work in the collection of dates

and statistics of our State mineral industries. No steps in this direction have ever been taken however. The "field-work" has been construed largely into getting descriptions of mines of interest mainly to their owners.

Thus it will be seen there is room for improvement in the methods of the Bureau but nothing so very radical as to call for abandoning it altogether. Should the Trustees be given greater power and wider duties, then more care should be exercised in their selection. This fact that a man has made money out of mines, or was at one time connected with them, should not alone make him eligible as a Trustee. His fitness for the position should be considered. Many who have been made Trustees have taken very little active interest, attending the meetings occasionally to pass on bills, etc., but giving slight attention to the conduct of affairs. Of the reports they know scarcely anything unless they see them in print. Possibly if invested with more authority, as the Governor suggests, they would take a more active part in the administration of the Bureau. But in that case there is even more need of having suitable men chosen. As there is no salary and no patronage, the position of Trustee of the State Mining Bureau has not been sought for, and the Governors who have made the appointments have done so more out of complacency than with reference to the ability or activity of the appointees.

People in the mining counties should, in the event of a further suggestion to abolish the Bureau, write to the Assemblymen and Senators of their respective counties, strenuously objecting. If no advocates for it come forward, and its enemies do, the natural inference among the legislators would be that it was not doing any good. But the Bureau has many friends all over the State who must rally to its support during the present crisis. The question as to who will be the State Mineralogist has nothing whatever to do with the matter. It is the institution itself which needs support. The Governor will select the man to take charge, and will not do so thoughtlessly, having taken interest enough in the Bureau to suggest the reforms referred to.

Citrus Fruits from Mining Counties.

The citrus fair of the northern district of California is now in progress in the Mechanics' Pavilion, the largest place of assembly in San Francisco. It would amaze some of the old-timers who arrived in the early days in Placer, Butte, Nevada, El Dorado, Yuba and other central northern counties to find such magnificent fruit coming from regions they thought worthless except for gold. In all these counties they still continue to mine, but they also raise many varieties of fruit, among which the oranges are conspicuous. For many years it was thought the citrus fruits could only grow south of Tehachapi pass, but experience has proven to the contrary, and the fruit ripens in some of these upper counties earlier than it does south. The old red ground of the foothills of the Sierra, gold-bearing though it is in places, furnishes the best of soil for the culture of the citrus fruits, now so important among the valued products of the State.

A tour through the Mechanics' Pavilion to-day is an education as to the resources and products of the State of California. It is a marvel both to the Californian and to the stranger. The variety of products, fruit and agricultural, is prodigious. The methods of exhibit are tasteful and satisfactory. The arrangement is splendid and even magnificent. Some displays are very pretentious and strike the beholder with an involuntary feeling of admiration, if not with positive awe. The several county exhibits are without exception in charge of gentlemen and ladies who take an active interest in showing their products, with their numerous and manifold beauties, to all who take the trouble to inspect or inquire. The success of the entire exhibition attests the care, capability and liberality of those who have it in charge.

The county exhibits are in the center of the great Mechanics' Pavilion, visible alike from the ground floor and from the gallery, and each takes up many hundred square feet. From the gallery, where a better perspective can be obtained than from any other point, the ensemble is unique, striking and even magnificent. First comes Placer, the Gateway County, which fully vindicates its appropriate pseudonym by a great triumphal arch whose constituent element appears to be wholly oranges. On the right is Yuba with its artistic windmill of oranges, nuts and lemons. On the left Colusa, with a small but excellent display, and Sacramento with its orange locomotive. At the rear is Butte county, with its great, orange Rock of Ages, fine market pavilion, and handsome grain and fruit palace. Butte county takes up more space than any other, having altogether perhaps 10,000 square feet. Humboldt, Sonoma, Alameda, San Luis Obispo, Sutter, Stanislaus are also represented. Ten years ago it was not thought that orange-trees would thrive in Placer county, which, as its name indicates, had and yet has for its chief industry the operation of mines. Its population depended very largely upon the development of its mineral riches for support, and immigration was attracted thither chiefly by interests and allurements of that kind. About ten years since, however, experiments were made with orange orchards, and it was found that they would produce a fruit of luscious and delicate flavor. From an experiment, orange cultivation rapidly developed into an industry of respectable

dimensions and permanent conditions, and to-day Placer county produces the orange in commercial quantities for export. It is already a source of revenue, and is destined to be a large factor in the growth and development of the county, and a heavy contributor to its wealth and prosperity.

It should be mentioned that Placer makes an auxiliary exhibit of dried and preserved fruits, which have found a station near the arch. It is varied and creditable, and is a fine showing of the county's citrus and other resources, outside the more pretentious and obtrusive fresh-fruit display.

The Placer county exhibit has already received the premium of \$250 for the "most original and attractive exhibit on the opening day." This is exclusive of citrus products. In many places in this county they can drift for gold underground and raise oranges on the surface, doing both farming and mining on the same ground.

Placer county comes first after entrance of the pavilion. The arch, as shown in the cut on the first page, is built on a most imposing and impressive place. It stretches from one side of the vacant space under the gallery to the other. Its dimensions are about 15x80 feet, at a guess. It has three openings—one main in the center and two at the side—and is of the familiar plan seen in all pictures of ancient Roman triumphs, and at our own Fourth of July and other important celebrations. It is well-proportioned and really artistic and finished in its architectural whole. It is in reality a rude wooden structure, but it is so completely and artfully covered with oranges that little of its real supporting timbers or framework is visible. Between 45,000 and 50,000 oranges were used in its make-up, placed in even rows with care and infinite labor. Yuba county has a number of fine displays, arranged and placed on exhibition by various towns and localities. One of the most impressive is that of Smartsville, which is a miniature representation of the California building at the World's Fair. It is the individual production of James K. O'Brien, superintendent of the entire citrus exhibit. It presents a handsome appearance, and the oranges are arranged so as to be displayed to the best advantage. Between 12,000 and 15,000 are required to cover the building. Smartsville is a famous gold-mining camp, but the land is devoted to a "golden fruit" in these days.

Brown's valley is represented by a gigantic bell, covered with oranges. Lemons are also prominent.

Wheatland has a picturesque Eiffel tower, about 12 feet high.

The county as a whole is represented by a full-size windmill, in which oranges, lemons, peanuts, prunes and figs are conspicuously shown. The fans of the wheel are made up largely of gilded peanuts. Windows, doors and other appliances of a genuine windmill are in their proper places and the likeness is carried out to the smallest particular. The wheel is operated by electricity. Surrounding the mill is a neat plot of made-ground, in which appear a pretty water-fall, grasses, mosses, displays of fruit and other pleasing things.

The Yuba county exhibit as a whole is a prominent and inviting part of the entire citrus show, and reflects credit upon the taste, care and liberality of those who got it up.

Sacramento's most unique exhibit is the "citrus locomotive." The locomotive, is built on the narrow-gauge principle, and is equipped with about 35,000 oranges, fastened on to a wooden structure with painstaking diligence and industry. There are also numerous lemons in the make-up, and dried prunes, figs and apricots, peanuts, walnuts, and even Chinese lemons. The dried fruits have been used in appropriate places for making letters, varying colors, and so on. The realistic effect is heightened in a very great degree by the use of real locomotive appliances, such as bell, piston, steam-gauge, oilcups, and signal lanterns.

Butte county, another of the famous mining counties of California, has the most extensive citrus display of any at the fair. That is to say, it occupies more space. It is one of the leading features of the entire exhibition, and has attracted general and most favorable attention. The chief portion is the "Rock of Ages," constructed by the town of Oroville. A "Rock of Ages" made up of oranges might seem an anomaly, but the effect is made realistic by a painted background, representing the stormy sea, and lowering clouds, and a frowning rock boldly appearing from the angry waters. The foreground is an enormous bed of oranges, with lemons arranged here and there in a very pretty manner. The "Rock of Ages" is placed at the rear of the pavilion. The structure is at least thirty feet high and forty feet broad. On the semi-circular frame at the top is a decoration of palm leaves, and under it the inscription "Rock of Ages," in ornamental text, each letter being made of oranges. The cross in the foreground, its base surrounded by rocks, ferns and running water, is also covered with the golden fruit. At the extreme apex of the arch is an electric star, and the whole scene is suffused by the blaze of a search light at night. At nine o'clock each night a tableau is presented, at which a young lady in white comes forth and clings to the cross, in the affecting fashion usually depicted in the familiar allegorical picture. The hand in the meantime plays the grand old hymn.

THE SAN JUAN COUNTRY.—A dispatch from Dandy Crossing, Utah, dated the 17th says: The Navajoes have driven out every party of prospectors crossing the San Juan river. David Menzies and his party made their way back on foot, the horses and pack outfit having been run off by the Indians. Menzies says the Indians are massing and mean trouble. Another dispatch from Colorado Springs, Col., dated Jan. 18th says: J. C. Cox, an old miner, has just returned from the San Juan gold fields. He confirms the statement that the story of a rich find of gold placers was the worst kind of a fake. He says gold is found but not in quantities to pay for mining by any method. Crowds still flock there, although the roads are

lined with hundreds of miners who are leaving. He says there is much privation in the camp. A notice offering \$5000 reward for John Hay, dead or alive, is conspicuously posted at intervals throughout the district. Hay is charged with having originated the fake.

Coast Industrial Notes.

A 50 BARREL a day petroleum flow has been struck at Newhall in a well 800 feet deep.

THE Buckley Lumber Company's mill at Tacoma was burned on the 15th, with a loss of \$20,000.

ANOTHER fine deposit of bituminous rock has been found, the new find being located on the coast about 20 miles below Santa Barbara.

ON Saturday last Bakersfield formally celebrated the completion of the East Side canal, and the formal opening of the Bakersfield and Asphalto railroad.

THE steam launch for the Mohican is being fitted at Mare Island Navy yard with a Ward boiler. The launch for the Independence has a new boiler of the Towne type.

THE total exports of lumber from this port in 1892 were 213,332,533 feet valued at \$495,492. Great Britain took most of this and Australia, Central America, Mexico and South Sea Islands also took large quantities.

NEWS has reached Spokane of the failure of the firm of Moore, Ish & Co., one of the largest general merchandise firms operating in the Okanogan mining country. They had stores at Conconully and Loomiston and also did a general banking business. The failure was due to a recent fire.

THE exports of salmon by water from San Francisco during the month of December aggregated 111,656 cases and 563 packages, the whole valued at \$520,956. For the year 1892 the total shipments were 758,487 cans. There were also 5946 packages of pickled salmon. The value of the shipments for the year were \$3,490,627.

THE Board of Supervisors have granted a franchise to Peter Tauphauss and others of San Francisco to build and maintain an electric railroad between Nevada City and Grass Valley. The *Transcript* says that the road will certainly be constructed, and with as little delay as possible, as surveyors will be put to work immediately to lay out the route preparatory to building the road. The parties obtaining the franchise have ample capital to carry through the enterprise.

A NEW industry has sprung up in the western part of Washington, the making of tannin extract from hemlock bark. The variety used, known as white hemlock, yields a very superior light colored extract, which gives leather a color that can hardly be distinguished from oak tan. The great richness of Washington hemlock is worthy of special note. A recent analysis, by one of the leading leather chemists of the United States shows that it carries 17.8 per cent. tannin, while that of Eastern States will not average over ten per cent.

THE sealers which recently left the port and commenced their course just outside the Golden Gate are having good luck. North coast steamer captains report that they never knew such an extensive or consolidated migration, and the early birds are catching worms at a great rate. The schooner Arthur I arrived with the news that the Emma Louise is in Drake's bay with over 200 skins as the result of a little less than two weeks' hunting. The other schooners that are putting out boats between here and Mendocino are the Edward E. Webster, Mary Brown and the Alexander.

SOUTHERN California growers have demonstrated that fresh vegetables grown in this State can be profitably shipped to the East. This result has more importance than the mere fact that vegetables can be remuneratively raised here for export. It means that settlers cultivating new land for orchard purposes can make their holding return them an income the first year. In setting out new orchards there is always ample room between the rows of young trees for planting small fruits, such as berries and vegetables, without interfering with the growth or development of the orchard. The trouble in the past has been to find a ready market for such product. This has now been secured and is sufficiently extensive to make improbable any oversupply.

Personal.

FRANK McLAUGHLIN, of Oroville, is in town for a while.

W. H. TAGGART, a mining man from Kingman, Arizona, is at the Lick House.

A. T. EMBICH, a mining man from Helena, Montana, is visiting the city with his brother.

W. L. WATTS, of the State Mining Bureau, says that the sandstone found near Sites, Colusa Co., is probably the best in the State.

C. W. BONYNGE, of London, who a number of years ago made a very large fortune out of the Comstock mines, is at the Grand.

MR. A. B. PAUL of Shasta county, who is passing the winter in this city, has taken an office for the present in Room 4, second floor of the Crocker building.

WM. B. WRIGHTMAN, of this city, has been appointed Bank Examiner for California, vice Chamberlain. Mr. Wrightman was for many years private secretary to the late Senator Hearst.

SUPERINTENDENT J. F. PARKS, who has made the Kennedy mine, Amador county, one of the best-paying mines of the coast, must feel happy. The cleanup of last month—\$68,000—was the largest in the history of the mine.

A BODY of ochre, used as a coloring material in paints, has been discovered near Muddleberry canyon, seven miles east of Lovelock, Nev.

Product of the Precious Metals in 1892.

Wells, Fargo & Co.'s Estimate for the Year.

John I. Valentine, president of Wells, Fargo & Co., in his circular on the precious metal product, says:

The following is our annual report of precious metals produced in the States and Territories west of the Missouri river (including British Columbia) during 1892, which shows in the aggregate: Gold, \$30,119,636; silver, \$50,607,601; copper, \$19,370,516; lead, \$11,433,947. Total gross receipts, \$111,531,700. The "commercial" value at which the several metals named herein have been estimated, is: silver, \$87 cts. per oz.; copper, 12 cts. per lb.; and lead, \$4.10 per cwt.

As in former reports, allowance must be made for probable variations from exact figures, by reason of constantly increasing facilities for transporting bullion, ores and base metals from the mines outside of the Express and the difficulty of getting entirely reliable data from private sources. Estimates obtained in this way are liable to be exaggerated and are, to a degree, guess work; but with some modifications on this account, made herein, the general results reached, while only approximately correct, may be accepted as the closest approximation possible under the circumstances.

STATES AND TERRITORIES.	Gold Dust & Bullion by Express.	Gold Dust & Bullion by other Conveyances.	Silver Bullion by Express.	Ores & Base Bullion by Freight.	Total.
California	\$8,961,488	\$1,400,000	\$351,139	\$886,571	\$11,599,196

The exports of silver during the past year to Japan, China, the Straits, etc., have been as follows: From London, \$54,226,465; from San Francisco, \$13,116,059. Total, \$67,342,524, against \$41,379,445 last year. Pounds sterling estimated at \$4.84.

CHICAGO papers are busily engaged in diffusing information that hotel and lodging rates at the World's Fair will be very reasonable and even cheap; and, in proof, submit the following as the average to be charged, ascertained by a systematic canvass of the city: Single room, single bed, one person, \$1.36; double room, double bed, one person, \$2.12; double room, double bed, two persons, \$2.70; double room, two double beds, two persons, \$3.50; double room, two double beds, three persons, \$4.15; double room, two double beds, four persons, \$5.50. The Chicago

press has unwittingly shown that the "gouge" is to be universally practiced by hotel and lodging-house keepers, and private landladies anxious to turn a more or less honest penny by renting rooms. The prices are outrageous. A respectable and comfortable room, for which in Chicago the charge will be \$2.12 per night, can be obtained in San Francisco for fifty cents.

Piru Mining District.

FAIRVIEW CAMP, PIRU DISTRICT, VENTURA CO.

TO THE EDITOR:—In one of my letters to the PRESS I stated that the White Mule Company was putting up a five-stamp quartz mill. I was so informed at that time, and part of the timber and engine were on the ground. But as Mr. Harbell, one of the owners of the mine, was up at Sacramento, attending the State Fair, he saw the Huntington Mill there on exhibition, and had some ore from the White Mule mine worked. He was so well pleased with the Huntington mill that he gave up the idea of putting up stamps, and now the Company has a Huntington 3-foot mill, a Woodbury concentrator, and a Huntington rock breaker and ore-feeder. The mill is built, and everything is in first-class shape to commence grinding out the yellow gold. Mr. Harry Mead superintended the work. He is a first-class millwright, and has had many years experience at the business. George Haylock and W. H. Carpenter are going to put up a mill on the Bunker Hill mine next spring, the mine being opened so as to show hundreds of tons of good paying ore in sight. The Fairview mine has the same class of ore as the Bunker Hill, and is on the same lode. There are several veins on each claim, but the one opened up on the Bunker Hill is 30 or 40 feet wide, assaying from two or three dollars up into the hundreds. I think it will average \$10 or \$15. If it does it is a good mine, as it can be worked very cheap, there being an abundance of good timber for mining purposes and for fuel. That is one great advantage we have in this district—plenty of wood and water for steam mills. Five miles south of this camp is the Piru creek, which furnishes a splendid water power, and the day will come when there will be dozens of mills in this district run by electricity; electrical plants being placed on the Piru and Lockwood creeks. The writer may not see it, but it will be done some day. Everything moves very slowly in this camp. The reason is, all the men who own mines are too poor to rush things, or at least most of them are, and if the mining law was changed as your correspondent, Mr. Ross E. Browne, suggests, they would not be able to pay \$50 cash annually to keep up some mining engineer; neither would there be any more good mines found while doing assessment work. Rich men and big corporations would soon have all the mineral land gobbled up and the poor prospector would go hungry for something to eat. The only chance that the prospectors here have had to get money to buy tools, powder, provisions and clothes, has been by working for men who live at a distance and own mining claims here. The prospector, by getting the assessment work to do, can live and have part of the year to do his own assessment work. Some of Mr. Browne's ideas are good enough, but I want to see the mining laws let alone. The United States mineral laws are all right, and the more they are "tinkered" with the worse it is for prospectors and miners and the better it suits lawyers and surveyors. Again, as to "the granting of extra lateral right to lode claims, i. e., the right to follow and work a lode on its dip into neighboring ground," I know of a good mine which has several thousand dollars worth of machinery and other improvements on it, that, if the owners were not allowed the privilege of following the vein across their side-line, the vein being on so slight a dip or incline, would not be of any value to them. I could put down a shaft just north of their side-line and get the best part of the vein, after they have spent their money following the vein to show me where to sink, and also how far I would have to go to strike their best ground. The law is right and just. I have already said too much, and want to hear from other prospectors on the subject. I am alluding to quartz veins, not placer or hydraulic claims. I. H.

PITTSBURGH COAL AND ITS COMPETITORS.—Pittsburgh coal operators, particularly those shipping by river complain of the growing competition of the Kanawha district and the fields of Kentucky, Illinois and Indiana and farther south of Alabama. In the first-named fields cheaper prices for mining, cheaper coal lands and shorter haulage enable the shipper to place his product in the Cincinnati and Louisville markets at a figure that about represents cost to the Pittsburgh operator. The Pittsburgh coal is conceded to be worth more money, being of greatly superior quality than its rivals, but the argument of the dealers in these markets is that the difference in the quality is equalized by the difference in price, and that goes with the consumer, who after all it is that pays for the coal. It is a fact that during the whole of the long dry season the highest price realized by a Pittsburgh operator for his coal was 8 cents, and that only in a few instances, the bulk going at 7½ cents. This one statement alone is sufficient to indicate how the river coal is holding its place in these markets, during former dry spells Pittsburgh coal easily realizing 10 and 12 cents. It is also a fact that when the two runs that went out on the rise the other day reached Cincinnati that all that was offered for it was 6½ cents. In some instances only 6 cents was bid.—Coal Trade Journal.

It appears that during the past year the production of beet sugar in California increased from 8,000,000 pounds of the previous year to nearly 23,000,000 pounds. The sugar industry is reaching such great proportions that it is likely Congress will meet strong opposition from a new and powerful interest if it attempts to abolish the sugar bounty.

The MacArthur-Forrest Process.

The Results of Work and Experience with Cyanide.

SAN FRANCISCO, Jan. 7, 1893.

TO THE EDITOR:—For several months past I have seen a good deal of literature on the cyanide process, some of which is above the average, and for the inquiring mind highly instructive—notably, the very able and valuable articles of Mr. Chas. H. Aaron; while many more show a creditable desire for information, and some a marked ignorance of the practical features of the process.

My object, in so long maintaining silence, was, that the many critics having their say, without comment, would possibly give me a lesson of value; but thus far I have not been much enlightened by their effusions. During my silence, I have read all, investigated not a little, and in consequence know more; and here I want to say to those who read my article as published in the MINING AND SCIENTIFIC PRESS of July 2, 1892, that I have nothing to take back, not a line to erase or change, but can add much more favorable material, and in a more convenient shape. Every day's practice has been my tutor, and thus I talk from what I know—not think. Allow me here to sum up a great deal, by saying that the cyanide process is coming to the front more rapidly than any new method ever has; for, up to date, many mills, in the various mining States, have adopted the process, while in South Africa it has made wonderful strides. There, the mills are large, some having tanks of 500 tons capacity each. Several new mills are now in progress, and one company has made contracts for working 35,000 tons per month by the process.

California has been considered a wide-awake mining State, but it has to arouse from its lethargic sleep, or be relegated to the rear. In fact, to-day, South Africa is producing more gold than the entire State of California, and yet we boast of possessing the largest area and most valuable goldfields of the world.

Like every new idea, this process has got to pass through the ordeal of defamation by those who have selfish interests to serve, and others who talk wisely on what they think they know. Some of my correspondents have asked why I do not denounce these critical writers against the process; and here I want to say, defending the moneyed interest of the process is not my fight. The Denver Co. is amply able to do that. My object in giving these articles to the public is for the betterment of the gold-producing interest, and to satisfy a laudable desire for information as to practical working. Why I take the interest in the process I do is from the fact that I have been cursed for over 30 years in looking after a vast lot of machinery, the majority of which, with this process, can be dispensed with, and at the same time get better results. But, says one, you are an "interested party." Mr. Geo. A. Garbutt's observations, as published in the MINING AND SCIENTIFIC PRESS of Nov. 12th are as good as a whole page: "By inference, their own statements would not be reliable were they interested; hence their distrust of others." For my part, the reader can estimate my words to suit himself; the best I can do is to give the public the benefit of my experience, although it is a fact, sensibly realized, that I have never been benefited by writing for the public.

All around I see apeings of the MacArthur-Forrest process; this is to be expected, and many will seek to defame the better, even at the expense of pushing forward an inferior one. No higher compliment can be paid the MacArthur-Forrest process than that others are seeking to imitate it. There will no doubt be many attempted improvements, but, as I see it, they must all be of a more expensive kind.

Certainly the process of to-day is cheapness and simplicity itself. What can be more simple than a plant where crushing the ore into tanks is about the only labor and machinery required, and the obtaining of a high per cent a certainty? With this system the millman has peace—he is not distracted by machinery getting out of order, and doubling expenses when laid up for repairs,—this goes right on percolating when you are asleep. In other words, you can run your mill daytime, and the production of gold runs itself at night, or as you may wish. Accepting the proposition that the "world moves," there will no doubt be modifications in some particulars, in fact I consider the "circulating" mode—for the majority of ore—quite an advanced step, if I did first introduce it, but this simply changes the mode of handling both ore and solution. So much for generalities; now for more valuable information.

There are no doubt some who have desired a detailed statement of our ton-working by this process. It is reasonable they should, and this is why it has not been done. After working a number of experimental lots, varying from 50 to 100 tons each, I started on a 500-ton run, intending to cover every important feature and to give the public full details of it; to this point samples of ore were taken regularly, value ascertained, extractions noted, etc., etc. During the time of this run our chemist and assayer was taken sick and writing up of the statistics in full form was delayed; when on the latter part of the run he was taken worse and left for San Francisco, where he died.

After his death I endeavored to work up the details of the run from his books, but found the figures so interwoven with the other work that I could not be certain of its absolute correctness, and abandoned the task. Since, I have had occasion to start a new mill on the process—every part new—and concluded to look after this short run myself, and investigate it in the most minute particular, and especially as the lot of ore was of a very difficult kind for extracting the metal from.

Not any of this ore would yield by general milling 30 per cent of its value. Twelve tons of this lot contained a small percentage of copper, generally objectionable on account of

too heavy a loss of cyanide. Still I concluded to get a lesson myself from working it, with every part of a mill free of one atom of gold belonging to any other run. It must be admitted by every millman of experience that the first run of any new mill is never as satisfactory as the after workings. The quantity of ore for treatment was 32 tons 894 pounds by weight, and having an assay value of \$576.43 or \$17.76 per ton. The result was as follows:

Value of bar.....	\$48.61	being 74	35-100 per cent
Left in solution.....	54.25	"	11 15-100 "
Left in tails.....	32.16	"	5 5-100 "
Leakage of tanks.....	50.49	"	8 75-100 "
Absorption, etc., say.....	.92	"	69-100 "
Totals.....	\$576.43		100 per cent.

By this it will be seen that 94.20-100 per cent was extracted and 85½ per cent saved, and this from ore of a troublesome kind for general mill work.

Gold left in solution could all have been taken up by another run through the precipitating vessels. Gold left in solution is not lost, and an entire precipitation of the gold matters but little when you are working your own ore; you get it next run, without loss of time or extra expense. Leakage of tanks makes quite an item, and but for this the extraction recoverable would have been over 90 per cent. The leakage was from wooden tanks—an abomination. You never can tell in the dry climate of California when they are tight or leaky. Latterly, I eschew them altogether; wooden tanks are cheaper to begin with, but the leakage item ever will condemn them; besides, they absorb both gold and cyanide. Iron tanks are the profitable ones in the end. Cyanide consumed in the above run was 148 21-100 pounds, being 4.53-100 pounds per ton, which, at 55 cents, makes the cost \$2.48 per ton.

Making detailed statements, as the above, is no small matter, either as to time or expense, as you have not only to make bars from the gold slimes, but to destroy all your zinc to ascertain the amount of gold deposited thereon. Measure all your solution, and test for the amount of gold and cyanide it contains, and this you can see means work and loss of time, to no purpose outside of information, and this is the reason so few tests are reported upon for the benefit of the "dear people." My plan of operation is to know the assay of tails after a certain number of solutions have been used, and if the work shows an extraction of from 85 to 95 per cent (according to grade of ore), I let the tails go, knowing full well I will find the metal somewhere; if not in the zinc to-day, it will be there to-morrow. You need not lose anything by this process when once dissolved and washed out, except by leakage and absorption (if you use wooden tanks). I hear a good deal about high extractions, and being unable to get the gold. They admit a high extraction; well, that is one very valuable point settled, and the most important one. A chemist or assayer who can make a correct assay and a high extraction, and then cannot find the gold, seems very odd to me. There is a great inconsistency in this, and my explanation would be, your starting-point is wrong. The greatest trouble, I find, is getting rock with enough gold in it.

In one article of the PRESS I read as follows: "There seems no difficulty in getting the gold into the solution, but there is a good deal of trouble in getting it out. The zinc shavings used by the MacArthur-Forrest process do not seem to accomplish the object—one finds gold wherever the solution flows." I do not find any of this difficulty in any essential particular; neither do I find gold precipitated wherever the solution flows. This is all nonsense, for if such were a fact a better precipitant than zinc shavings would soon be discovered. After reading this paragraph, I took out eight feet of iron pipe through which about \$1000 of solution had flowed, and had the same thoroughly cleaned, the water evaporated, and the residue put into a lead button and the value ascertained to a fraction; the result was 14 mgs. of gold, value about nine-tenths of one cent! To test this matter further, I washed the sediment of the conveying-trough of one set of percolating tanks, 24 feet long, and through which over \$1000 had run as gold in solution. The sediment weighed, when dry, 9¾ ounces. The metal from this was thrown down into a lead button so as to be sure of getting all the gold, the button cupelled, and there was obtained as a result 17.667 mgs. of gold; value, 1 cent 1¾ mills.

I hear a number of queer stories; some go so far as to say they get a high extraction and then cannot find any gold in the solution. This is the worst yet. To take out something and nothing is obtained is a new law in chemistry, and certainly upsets the scientific axiom that nothing is lost. It is all bosh. Errors are never in the manipulator; it's always the process.

Some have said to me, "You have had good luck with the process." It is not good luck at all. It is understanding what to do, and seeing it is done, or doing it yourself. If you are going to work a chemical process, you must obey the law governing it, and nothing is more certain than true results.

To one unaccustomed to a chemical manipulation of ore, it may appear intricate, and that it requires great chemical knowledge, which all miners do not possess; but such is not the case. The process is decidedly more simple, and gives less trouble than an ordinary amalgamating and concentrating mill (outside of the assay department). You simply want a knowledge as to what to do, and this is readily "picked up." There is nothing difficult about it when you once understand it.

There are no doubt instances of failures, that should have been successes, occasioned from this lack of knowledge of details, and especially caring for the gold when deposited and the putting of same into bars. There never was any new system put before the public with so little instruction for a successful outcome, and the wonder is, that under such circumstances, the process has made the advancement it has. From the first there has been too much haphazard way of handling the process, which should not be permitted, instead of a well-conceived and perfected plan of construction and operation. As for a mill, outside of your reducing machinery, there is a good deal to con-

sider for economy of labor in handling both ore and solution. The construction is comparatively inexpensive; at the same time, position of tanks, their purpose and relation, is a very important part. Before starting for the erection of a plant, a well-studied plan should be mapped out. While the process is simple, efficient and easy, when you are running in the right channel, it is apt to bring disappointment when you deviate from the law and start out on some legerdmain work of your own.

Some object to the use of zinc shavings for precipitating the gold. What difference does it make so you get the gold at a trifling cost? I think it will be some time before the present plan will be bettered. With us it does the business quite satisfactory, though at the same time I am ever ready to take advanced steps, when better things present themselves. In the matter of precipitating vessels, you do not want to use wooden ones for economy sake. The white porcelain vessels, as made by the Toronto Pottery Co., Toronto, Ohio, and sold by J. Caire, 521 Market street, San Francisco, are decidedly preferable. They are non-absorbent, and the precipitation is a great deal more active than with the wooden boxes, at least it seems so to me, and I have used both. In these vessels I have had the zinc so heavily loaded with gold that it seemed apparently a web of it, all bright and beautiful. But, says one, we cannot get fine bullion. I can, and why not you? On a trial test I made one bar 994 fine from the "gold slimes" as taken from the precipitating boxes, and this without refining; but I do not care to make bullion so fine—mintable is fine enough, 600. According to the size of the screen used for taking out your gold slimes, will be the fineness of your bar, properly fluxed.

Strength of solution for general gold ores is a branch of the subject to which I have given a good deal of attention. According to instructions I started working with a one per cent solution, and tested on 50 and 100 ton lots at various percentages (on same ore) down to ¼ of 1 per cent, with results very near the same, provided a corresponding increase of time was given in the tanks for dissolving and percolation. It is a settled fact in my mind that the majority of ores at all suitable for the process can be more profitably worked at per cents running from ½ of 1 per cent down to say 15-100 of one per cent.

For quick work a strong solution economizes time; a weaker solution economizes cyanide. Tanks are cheap, and a plentiful supply of them will produce as much bullion, at less cost for working, than fewer tanks with stronger solution. This fact it is well to bear in mind when considering the erection of a plant, and here it is well to remark that calculations made heretofore as to expense of cyanide for working have been based on a one-per-cent solution, so you see that a lower solution, doing as good work, with a fraction more time, is quite a reduction in cyanide expense account. In South Africa, my correspondent informs me that they do most of their work with a solution varying from 20 to 40-100 of 1 per cent in strength.

The loss of cyanide in passing through the zinc depends on the strength of it; as to the destruction of the zinc, that is merely a trifle in dollars and cents. I like to see it pass away rapidly; two pounds of gold, theoretically, will destroy one pound of zinc shavings. To me it is always a very agreeable loss, and about the only loss I know of that gives any satisfaction.

As to the matter of dissolved zinc in the solution being a detriment, as yet I have not observed it; possibly after a given time it might be best to start fresh again.

Some say the process is not suitable for coarse gold. I accepted this idea at first, but have changed my mind on this point, and for this reason: Where the rock is impregnated with coarse gold there is more or less fine, and more, possibly, than it would cost to work the ore, if not a good deal more. This gold, when working the ordinary way for the coarse gold, is lost, while by using the wet or "circulating" plan your coarse gold can be taken up before it reaches the tanks, and thus you get both the coarse and fine gold. Even where you crush dry, and all goes into the tanks together, the same end can be accomplished by taking care when washing out your tanks and being prepared for taking up the coarser gold, and that too coarse for dissolving in profitable time. I made two trials on this point; by running the tails through the "Robinson rifles," all the gold was retained in the three upper rifles, the first the most, of course. I panned 13 rifles separately, so as to be sure. I also had a well-prepared silver plate below the first ten rifles, and not a speck of gold was retained by it.

As to the matter of fine gold, I have written a great deal within the past 35 years on this subject, and yet I have not realized, fully, all the facts that from time to time come up in reference to it. Recent tests, as made by Mr. J. H. Morton, manager of the Mammoth mine of Shasta county, gives quite a valuable lesson on the fine-gold question. Mr. Morton percolated a given quantity of clear water through ten pounds of ore of medium value, and extracted from same 48¾ mgs. of gold and silver, the gold being 22 1-10 mgs. Some years ago I read an account of some experiments to the same point, but passed it by as being possible but hardly realized it. This can, however, be considered as the starting-point for fine gold; and such being the fact, then comes the query how much gold of all grades of fineness is there up to what we denominate coarse gold. When the fine-gold question is fully realized by the millman, then the gold product will be increased, for then he will adapt such ways as secures all of it.

As to the matter of wet or dry reduction of ores, I am decidedly in favor of the wet, using the solution in the battery, and more especially as I see what can be accomplished with a low per cent of cyanide. I will say, however, that dry reduction is always on the safe side. Dry reduction is a big nuisance, destructive to both machinery and men; then what is the use of crushing dry when ore is not to be roasted? You crush dry and then add the solution. My plan is to crush with your weaker and strengthen up in the tanks, if the ore requires a stronger solution. If you use the barrel system, then it is well enough to crush dry. One objects to wet reduction in battery on account of

making slimes. This is the strongest objection that can be urged against it, but this disadvantage I will overcome by low discharge batteries. I work a high discharge and have more or less slimes, but the slime trouble I have fully overcome. One of the mills reduces the ore dry, so I have the whole matter before me to judge from. The dry mill makes more granulated ore, consequently less slime, and percolates some better I admit. Still, the difference, all things considered, inclines me to the wet way, especially as I manage the slimes with ease. I wish, before closing, to impress on the minds of my readers that, in my observations in reference to ores, I refer only to those suitable for the process; all are not, but the majority of gold ore is, yet no one should venture on a plant without testing as to their fitness.

Thus I give the public the results, experiences, thoughts and conclusions of months of labor and thousands of dollars of expense to gain it. If appreciated, it is my pleasure.

ALMARIN B. PAUL.

How Ore is Purchased.

In reply to a correspondent who asked how smelters figure on the smelting charge on ore, or the price to be paid for it, the *Mining Industry and Tradesman* gives herewith the usual rule. Different smelters vary the method a little, but reach practically the same result.

The ore, when it is received, is analyzed for silica, iron, lime, zinc, manganese, or other metalloids or metals it may contain in addition to its assay for gold, silver, lead or copper. Each of these ingredients is beneficial or injurious in a smelting charge. Those which are beneficial are credited with a certain amount for each unit, or per cent, in which they occur in an ore, and those which are injurious are charged with a certain per cent. Silica and zinc are charged for, and iron, lime, gold, lead and copper, when the three latter occur in quantities too small to be paid for, are all credited with some value. Under the scale of prices adopted by smelters, lead, when it occurs in a less quantity than 10 per cent., is not paid for. The same is true as to copper below 2 per cent. and gold below one-twentieth of an ounce per ton. The miner usually supposes that on account of this schedule of prices he is never paid for these metals his ore may contain, if their quantity falls below the percentage or value stated. But he does get pay, in lower smelting charges.

As for silica and iron, equal quantities of each are counted as offsetting each other. If an ore contains more silica than iron, it carries an excess of silica, and each unit or per cent. of the excess is charged for. If it carries more iron than silica, the excess of iron is paid for on the same basis. At the present time iron excess is generally paid for at the rate of 15 cents for each unit, and the excess of silica is charged for at the same rate.

Let it be assumed that an ore carries silica 30 per cent., iron 20 per cent., lead 8 per cent., zinc 12 per cent., gold .04 of an ounce and silver 100 ounces per ton. The balance is sulphur, which is mostly eliminated by roasting, for which there is a uniform charge on all ore requiring roasting of \$2.50 per ton. In estimating the cost of smelting, the charge against the ore would be as follows:

10 per cent. silica excess.....	\$ 1.50
12 " " zinc.....	6.00
Roasting.....	2.50
Smelting.....	4.50
Total.....	\$14.50
The credits would be	
8 per cent. lead at 20 cents.....	\$ 1.60
.04 gold at \$19 an ounce.....	.76
100 ozs. silver at 82 cents less 5 per cent.....	77.90
	\$80.26
Less.....	14.50
Price paid per ton.....	\$65.76

As usually stated the silver only in such ore would be paid for at 95 per cent. of its New York quotation on the day of sale. That quotation would make its value, as stated, \$77.90 per ton, and there would be paid for it \$65.76 per ton, making the apparent smelting charge the difference between the two, or \$12.14 per ton. It will be seen that the owner of such ore gets pay for its lead and gold contents, notwithstanding the buyers do not profess to pay for them when they are found in these small quantities.

Of course ore buyers vary their bids for ore, just as they may need the particular ore on which they are bidding. One smelter may need a siliceous ore, while others do not. In that case the smelter requiring such ore might not charge the silica excess with \$1.50, in which case his apparent smelting charge would be less than that of other smelters which laid upon it that charge. Again a smelter might be in such great need of lead ore that he might be willing to credit the ore with more than 20 cents for each unit of its lead contents, even though it fell below 10 per cent.

Again when different smelters are bidding on a lot of ore, as they do on all lots sold through the public sampling works, each one making his own analysis, there may be a difference in the analysis on silica, zinc, iron or any other of its contents, of even 1 per cent. or a fraction of an ounce of silver, and in such cases there will be a corresponding difference in bids, from men who calculate on the same basis, at the same prices. It is thus that bids on the same ore may differ considerably.

AT Great Falls, Montana, the Sand Coulee Coal Co., is taking out 1,500 tons of coal a day from their Sand Coulee mine, ten miles from the city, and there are a large number of mines being worked that are taking out smaller quantities. The Great Falls coal is used all over the State of Montana and a great deal in the Dakotas. It is an excellent steam coal, and some of the veins are a superior coking coal.

Mechanical Progress.

Silencing Gas and Steam Engine Exhausts.

The London *Journal* "notes" that M. Simon has communicated to *L'Electricien* a suggestion for reducing the noise of gas engine exhausts. He points out that the noise is of two kinds. There is, first, a blow at every discharge; and, secondly, a distinctive note given out by the escape of the gases under pressure, which is always produced whether the exhaust is spasmodic or regular. As a matter of practice, the shock of the first can be mitigated by exhausting into chambers which play the same part as the air chambers of double-acting pumps. Unfortunately this remedy is limited in application by the danger of filling large receivers with gases that may have escaped combustion in the cylinder, and thus compose an explosive mixture. Moreover, this method of regulation creates back pressure, and therefore, for two reasons, it is of limited applicability. M. Simon says that what is wanted is a gradual and insensible diminution of the average velocity of the exhaust gases. The variations of pressure, and consequently volume, would thus be rendered very small, and the violence of the blows would be diminished; while the exhaust gases, having a lower velocity, would no longer give a loud noise.

A system of very acute-angled, conical tubes has been tried by M. Simon himself and others, with the idea that the insensibly increasing cross-section should produce a gradual diminution of velocity. Unfortunately, when the diameter approaches a certain value, the velocity of the gases is no longer equal over any given section, owing to the friction of the sides, which creates a series of vortices that make the tubes quiver, and so produces an effect the reverse of what is intended. M. Simon has substituted for these cones a single, straight pipe, split for a distance of about two meters. The opening is very narrow at the bottom, and widens out until it attains a width equal to the diameter of the tube. The effect produced is remarkable when the right width for the cut has been hit upon; and this can only be done by the method of trial and error. It is no easy matter to split a tube in this way by means of ordinary tools, and alterations are a long and troublesome job. M. Simon has considerably simplified matters by giving the tube a long saw-cut lengthwise; the two halves being then opened out and kept apart by wedges and rings. From such an outlet the puff of exhaust gas spreads out like a fan, and the passage from the tube to the open air is very gradual. Such is the method, at once simple and cheap, which M. Simon has applied to his own satisfaction, and particularly to that of his neighbors, whose quiet was broken by his gas engine. The same device will effectually reduce the noise of steam escaping from a pipe.

Wide or Narrow Tires.

Our readers will be interested in the following from Clem Studebaker, of Studebaker Bros. Manufacturing Co. He says: "There can be no doubt that the general adoption of wide tires would work less harm to poor roads than would narrow tires. Broad tires for wagons, of any width that would be practical, would not, in my opinion make good roads. They will simply have less tendency to cut up poor roads than would the narrow tire. The harm to wagon-roads commonly occurs when the surface is saturated with rain and the road-bed is soft and yielding. At such times loaded vehicles fitted with wheels with narrow tires cut out ruts in the roadway more or less deep, according to the length of the wet spell and the frequency of the passage of such vehicles. When, however, the road-bed is solid and care is taken to promptly fill up inequalities which may be created by reason of the wear and tear of the surface, in such event narrow tires, to all intents and purposes, are no disadvantage to the road-bed, while they are unquestionably of greater advantage to the vehicle. Narrow tires tend to lighten draft in drawing loads over smooth roads and over soft roads. Over surfaces that are sandy or yielding in their nature the wide-tire wagons give the best results. The wide-tire wagons are accordingly better for general field use. We have, by the aid of a dynamometer, made a series of exhaustive experiments with the wide and narrow-tire wagons, and the result of these experiments justifies the statement contained in the foregoing.

"The supply of timber for felloes for wide-tire wagons is less abundant than that

which is suitable for narrow tires. On this account wide-tire wagons are more expensive than those which have the usual tire, and in case of a greatly-increased demand for them, the timber supply of this nature already being somewhat scarce, the tendency will be to still higher prices for wide-tire wagons."

A Trade a Necessity.

Every practical man is often asked by persons in other professions as to the advisability of having their sons taught, and, if a trade, what trade? Now, no matter what may be the social development of the near future, says the *Manufacturers' Record*, whether the present order or society shall be conserved or a new order shall be inaugurated, it is advisable that every boy shall be able to support himself by his hands, and do it as well as he can, by having them trained to the greatest skill they are capable of acquiring; for, if there be no change in the order or classes of society as they now exist, there may be changes in the circumstances of the individual, so that one who to-day adorns the summit of the highest class in society may next year disgrace the calling of a beggar by a failure to make it support him.

This condition is of such frequent occurrence that it may be said to stand across the future of every man as rather more than a possibility. Hence, if a man were master of any modern trade no circumstance could fall upon him hard enough to crush him. Therefore, a trade should be considered a necessity to any man in any condition. The trade to teach a boy is often difficult to decide, but to the right boy the machinist's trade is the best, for in the future, if advance continues to be made on present lines, all things will be made by machinery and all workmen will either be machine makers or machine tenders.

A machine maker must be very skillful, but a machine tender may need but little skill and may command inferior pay; hence, it is fair to assume that the skilled machinist will maintain his superiority hereafter as in the past. As an art, machine building has no equal; it rests solidly on the necessities of the human race; it extends above all other arts and demands of science its most perfect work.—*Manufacturers' Record*.

A STRONG VESSEL FOR THE ARCTIC.—Dr. Nansen's Arctic exploring ship *Fram* was launched at Laurin, Norway, on Oct. 26th, and is thus described in *Engineering*: Length on keel, 101.7 ft.; on water line, 13.2; on deck, 128 ft.; greatest width, 36 ft.; draft, light, 12.3 ft.; displacement, 530 tons. The keel is in two pieces, 14x14 ins., and the covering is 11 ins. thick. The keel is American oak, and the other timbers Italian oak, with the intervals between the timbers filled with a mixture of pitch, tar and sawdust. The inside lining is pitch pine from four to eight inches thick. The outer sheathing is in three layers, of three-inch oak plank, then four-inch oak and finally an "ice cover" of three to six inches of greenheart. The ship's sides will thus vary in thickness from 27 to 30½ ins., and the oak bow is four ft. thick. Various beams and cross-stays strengthen the vessel inside. The *Fram* is pointed fore and aft, and is there further protected by iron-plating. The engine is of 169 I. HP., capable of imparting a speed of six knots, and the coal supply is good for three to four months' continuous steaming. She is rigged as a three-masted schooner. The whole aim of Dr. Nansen has been to construct a strong ship that will lift if pinched between ice floes—and he seems to have succeeded in this aim as near as man can. He will start on his "drift across the North Pole" in June, 1893, sailing direct for Nova Zembla; then to the mouth of the Lena river, and northward from that point until the ice-pack renders navigation impossible.

CANALS are getting to receive much notice from the electric railway engineer, from the fact that almost the same class of machinery is being constructed for use on several of our leading canals as on railways. Along the towpath where the canal horse used to plod even more wearily than his street-railway confrere, modern engineering will construct a trolley-line, and the driver will exchange his lash for an electrical switch-handle. This field is not merely theoretical; the project has been tried and found eminently practical, and seems destined to become of wide commercial interest in the near future. On this head Gov. Flower says in his annual message to the New York Assembly: "Ample water-power for the generation of electricity is accessible along the line of the Erie Canal and could be utilized without great expense."

Scientific Progress.

Dr. Gilbert on Evolution of the Moon.

[At a meeting of the National Academy of Sciences, held at Baltimore, November, 1892, D. K. G. Gilbert, of the U. S. Geological Survey, presented a memoir on the Evolution of the Moon. An abstract of this paper is given in the *American Naturalist* for December, and is reprinted below. In this connection the reader should refer to these publications, volume IV, page 37, where an observation of Dr. Gilbert's on a crater in Arizona is described. This crater was actually formed by a falling meteor. So far as I know, Dr. Gilbert is the first geologist of high standing to give his authority to the hypothesis that lunar craters have, in general, been formed by the bombardment of the lunar surface by meteorites. My own studies on moon photographs do not lead me to the same conclusion. I hope that some of the selenographers of the society, Messrs. Weiner, Elger, Ranyard, and others, may be willing to treat this subject in the publications.—E. S. H.]

Dr. Gilbert said in part: The surface of the moon, like that of the earth, is diversified by plains, uplands and mountains, and these various features have special characters in which they differ from those of the earth. The plains lie lower than other portions of the surface, and are distinguished by their darker color.

By those who have mapped the surface of the moon, they are called seas, but the word is used in a figurative sense, for it is well understood that there is no water on the moon. The mountains are usually in the form of rings, each ring inclosing a hollow, and to this form the name crater is given. They are scattered over the surface of the plains, and on the uplands they are thickly set, overlapping one another in every variety of relation. They are of all sizes, from the smallest that the telescope can discern to a diameter of several hundred miles. Those of medium and larger size are usually characterized by a smooth circular plain in the interior and a hill or group of hills rising in the center of the plain. They differ from the craters of the earth in various ways, especially in the fact that their bottoms are below the level of the surrounding country, and in the fact that the central hill bears no crater on its summit.

The origin of these craters has been the subject of many theories. Despite their marked peculiarities of form, they have more commonly been ascribed to volcanic action; but they have also been referred to the bursting of gigantic bubbles, to the evaporation of water and its accumulation about the point of evaporation, as ice, and to the impact of bodies from without. Personally, I favor the last-mentioned explanation, but I differ from other writers in respect to the origin of the colliding bodies. It has been previously surmised that these might be rocks hurled from terrestrial volcanoes; that they might be meteors from the recesses of space, such as are continually burned in the upper layers of our atmosphere, giving rise to shooting stars, and that they might be aggregates of such meteors constituting balls of cosmic dust. Now, my idea of their origin is based upon the phenomena of the planet *Saturn* and its ring. About that planet is a disc-like ring which astronomers believe to be constituted of an indefinitely large number of very small bodies revolving about the planet in parallel orbits—a symmetrically-shaped form of small satellites. Assume that a similar ring of minute satellites once encircled the earth, and that those gradually became aggregated into a smaller number of larger satellites, and eventually into a single satellite—the moon. The craters mark the spots where the last of the small bodies collided with the surface when they finally lost their independence and joined the larger body.—Publication of Astronomical Society of the Pacific.

ALUMINIUM HORSESHOES—Russia has tried an experiment with aluminium shoes for cavalry horses, which will, no doubt, prove especially interesting to the owner of Nancy Hanks and other flyers. A few horses in the Finland dragoons were shod with one aluminium shoe and three iron shoes each, the former being on the fore foot in some cases and on the hind foot in others. The experiments lasted six weeks, and showed that the aluminium shoes lasted longer and preserved the foot better than the iron ones. No aluminium shoes broke, and they were used over again for reshoeing the horses. Moreover, they were worked over hard and very stony ground. The most important fact of all is that aluminium horseshoes are only one-third to one-fourth the weight of iron shoes.

Converting Heat Into Work.

In a paper recently read before the Manchester Association of Engineers, B. H. Thwaite, C. E., of Liverpool, discussed the economic possibilities of the generation of electromotive force in the coal fields and its application to industrial centers. In defining the most economic and practically ideal method of converting heat into work with the mechanical facts at present available, he says the procedure that will give this ideal method to fulfill the highest practical standard of efficiency and satisfy the exigencies of duty is as follows: 1st. The conversion of the solid fuel into a gaseous condition. 2d. The abstraction of the nitrogenous value from the fuel, and its conversion into a condition suitable for agricultural fertilization. 3d. The direct combustion of such gaseous fuel in the combustion cylinder of a gas motor, for the conversion of the thermic into dynamic energy. 4th. The transformation or transmutation of this dynamic into electric energy, or into electromotive force.

The ultimate possible results of a fuel-gas and gas-motor plant, on a large scale, is, that with such a plant, the dynamic power enclosed in the indicated card of pressure of a cylinder will be equivalent to the raising or elevation of 33,000 pounds one foot high in one minute, which may be obtained with an expenditure of from $\frac{1}{8}$ to 1 pound of solid fuel. That the fertilizing value from this fuel should be equivalent to the supply per ton of fuel of the equivalent of the nitrogen to that contained in 22 pounds to 28 pounds or more of ammonia sulphate. At present these conditions cannot be economically obtained from any other form of motor-generating procedure or plant than a gas engine. The procedure of the steam-engine method has an associated loss far greater than the gas engine; and although it is possible to convert the fuel into a gaseous condition and recover the nitrogen, there are losses attending the employment of such a procedure that partly neutralize the gain. It must be obvious to any one that direct and perfect combustion actually inside the walls of a motor cylinder must be more economic than the combustion, more or less perfect, in the flues of a steam boiler, even if effected under the most favorable conditions. Besides the fundamental advantages of the gas plant and gas-motor procedure, the instrument itself is more effective in its useful disposal of work represented by the indicated energy. Take the indicated energy of both the gas and the steam motor and compare it with that available for external work; it will be found that the former is very much more efficient. There is an important advantage in relatively small-power gas engines—the pulsations of piston effect could be so arranged that their effect on the supply would be unappreciable. In the arrangement of the plant for the projected coal field generating stations, gas motors of 300-horsepower are intended to be used, a pair of these engines being allotted to each alternating current machine, coupled direct, one engine driving the armature in one direction, and the other the field magnets in a contrary direction.

Electricity and Gas.

One often hears the statement that electricity for lighting purposes is making such headway that by it the use of gas is being displaced and less gas is being used. A careful study into the great strides made by the gas business since electric-lighting has been introduced will show that such is not true. Most of the large gas companies both here and in Europe have increased their plants materially during the past few years and continue to do so.

In Berlin, Germany, the central electric stations supply at least 100,000 lamps besides a large number of private installations; and notwithstanding this, the consumption of gas has steadily increased and the corporation of Berlin has recently decided to build another gas plant with a capacity of about 12,400,000 per day. In Leipzig and other German cities there has been a proportionate increase. For illustrations we do not need to go away from home. The gas companies in this and other large New England cities have all increased their plants.

If there was no such thing as electric-lighting, the consumption of gas would most likely be greater than it is, yet it is surprising how the introduction of electricity is always attended with an increased demand for gas. One of the principal reasons for this is the cultivation of the public taste up to a higher standard of illumination.

The electric light is so fine an illuminant, and with its use so much better results are obtained than with the use of old methods that the users of gas desire a higher candlepower and better gas and use more of it than they formerly did.—Boston Commercial Bulletin.

Useful Information.

A Change for the Better.

As old people fondly look back on the days of their youth, and say that such days were fraught with more of sensible and pleasurable living than is experienced by the rising generation, so do many of our veteran mechanics delude themselves by thinking that when they learned their trade, under conditions far more narrow and crude than those belonging to the advancement and greater enlightenment of the present day, men who followed mechanical vocations were better off and had more promising opportunities than they now do. No doubt there is a good deal to make such reasoning appear plausible. Thirty or forty years ago small machine shops were scattered thickly throughout the country, and many a mechanic, on a contracted scale, conducted an independent business for himself. Every town and village in the country had one or more clever individuals who, with the few rude tools and appliances of the times, did the "tinkering" for their neighbors. There was a deal of mechanical work done by hand, and to the old stagers it seems as if men then obtained employment more generally than than in these days, in which labor-saving machinery has such extensive usage. But if they stop to think, they would perceive that as many, if not more, individuals in proportion to the number of inhabitants, are at the present time engaged in mechanical pursuits. There has been a concentration of labor, that is all. The small shops have disappeared, but large establishments, containing new and improved machinery of all kinds, requiring for its guidance many hands, have supplanted them, and surpassed them to an immense extent in amount of work performed. It may be said, to roughly illustrate, that men now work in gangs and under a system of concentration, whereas formerly labor was more generally diffused among individuals who worked independently of each other.—Machinery.

Repairing a Broken Steamship Shaft.

The news that the Cunard steamer "Umbria" was drifting in midocean during a raging winter storm while the engineer made repairs on a broken shaft brought great relief to those who had friends on board the delayed vessel, but aroused a vast deal of curiosity among engineers everywhere as to how a broken shaft could be mended with the tools and material available on board the ship. Probably some 15,000 h. p. is transmitted from the "Umbria's" engines to her propeller by means of the shaft. To repair a break in this great cylinder, which is some 26 ins. in diameter, in such a manner as to enable it to transmit a small part even of the engine's power would appear to be practically impossible. A torsional strain which snaps a section of solid metal nearly 4 sq. ft. in area is not to be controlled by any weak makeshift.

The solution of the puzzle was not known until the "Umbria" herself arrived in port. It appeared that the fracture took place in the thrust-bearing between two of the flanges. The irregular running attracted the attention of the engineer, who stopped the engines, took off the thrust-bearing cap and found that a break had occurred extending about three-fourths through the shaft. The opposite flanges, between which the break occurred, were cut into and grooves were made in which heavy bolts were placed and held by straps passing around the shaft. Published accounts give the diameter of the bolts as 6 ins. By this expedient a coupling was made of sufficient strength to transmit the power from the engines to the screw when running at a 6 to 10 knot speed.

THE first paper of which mention is made was manufactured from papyrus in Alexandria, and was used by the nations living upon the shores of the Mediterranean. The art of making paper from fibrous matter reduced to a pulp in water is supposed to have been discovered by the Chinese about 1800 years ago. The Saracens, it is thought, acquired the art of making cotton paper about the year 704. The oldest manuscript written upon paper of this kind is in the Bodleian collection of the British Museum, and bears date 1409. In 1085, paper was made of rags instead of raw cotton. A specimen of linen paper is found bearing date 1100. In 1390, a papermill was established at Nuremberg by Ulman Stromer, operated by two rollers which set 18 stampers in motion. The first papermill in America was established by Wm. Rittinghuyzen and Wm. Bradford, on a small stream called Paper Mill Run, near Philadelphia; the second in 1710, at Germantown,

Pa. In 1729 a papermill was built upon Chester creek, Pa. The first papermill in Massachusetts was built at Milton in 1730. At the beginning of the Revolution there were three small mills in Massachusetts and one in Rhode Island. Now, large quantities of paper are made in this country and exported to England, Ireland, Australia, Mexico and the West Indies.

CAST-IRON COLUMNS.—In connection with the growing disfavor with which cast-iron columns are regarded in buildings, it is remarked that if pattern-makers, molders and founders were more careful, the number of failures of cast-iron columns might be greatly reduced. A molding may weaken a cast column by drawing away metal from the interior or shell proper. Sometimes a molding had better be cast separately and bolted on. Experiments made some time ago in Germany may be recalled, where two columns, one of cast and the other of wrought-iron, were equally loaded and subjected to a temperature first of 300 degrees Centigrade, then of 600 degrees, while streams of water were played upon them. It was found that the cast-iron pillars were much damaged and cracked, but did not fail, while those of wrought-iron were bent before a red heat was reached, and were so twisted when cold water was poured on them that they failed.—American Manufacturer.

POWER TRANSMISSION SCHEME.—A great electric power transmission scheme is being discussed in England. Mr. B. H. Thwait, the originator of the scheme, proposes to burn coal at the pit's mouth for the generation of power, and transmit this power electrically to the principal cities and manufacturing centers of England. The power would be generated by gas engines consuming only $\frac{1}{2}$ to 1 lb. of coal per horsepower-hour, and the residual products of the coal would all be saved and shipped by short haul to the agricultural districts, where they find their chief use as fertilizers. The cost of small installations of motive power (below 20 H.P.) in London is said to be from \$50 to \$90 per horsepower per annum. Mr. Thwait claims that electrical energy can be generated in the South Yorkshire coal fields and transmitted to London, a distance of 100 miles, at a cost of only \$22 to \$25 per horsepower for 3000 working hours per annum.

TIME TABLE FOR 1893.—Here is a time table for 1893:—Lent begins February 15 and ends with Easter Sunday, April 2; Washington's birthday, February 22, is on Wednesday; inauguration of the President, Saturday, March 4; St. Patrick's day, March 17, Friday; Fourth of July, Tuesday; Labor day, Monday, September 4; Christmas, December 25, Monday. It will be seen that Mr. Cleveland will have a chance to rest Sunday, March 5, and then to begin bright and early Monday morning to "set things to rights."

CATS, according to the old tradition, have nine lives, but they are not the only creatures that enjoy such a plurality. Infusoria have been dried and restored to life by moistening, after remaining inert dust for 27 years, and the drying and resuscitation have been successfully tried eleven times on one lot of rotifers. Frogs and many fishes suffer no injury from freezing solid, while, in a few cases, even warm-blooded animals have been restored to life after apparent death from freezing.

ALUMINIUM.—"Sebrof," in a recent number of *Engineering*, states that there is ten times more aluminium in the world than there is iron, lead, copper, zinc, nickel, gold and silver combined. He furthermore states that Dr. Meyer, of Berlin, has discovered a process by which the metal can be produced at about four cents per pound; (in 1828 the price was \$5000 per pound) the price to-day is about \$1 per pound.

ALUMINIUM SLATE PENCILS.—A new use of "the metal of the future" is announced, a German company having recently been started to make aluminium slate-pencils. The writing is stated to be as clear as with an ordinary slate-pencil and to be as easily erased. A Major von Sillich is said to have first discovered that aluminium makes a stroke on a slate.

EVERY oyster has a mouth, a heart, a liver, a stomach, besides many curiously devised little intestines and other organs, necessary organs such as would be handy to a living, moving, intelligent creature. The mouth is at the end of the shell, near the hinge, and adjoining the toothed portion of the oyster's pearly covering.

NEW DISCOVERY.

Mines Revived and Miners Enriched.
By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. Tabor, Pres.; LEONARD COW, V. Pres.; H. A. JONES, 2d V. Pres.; P. GEO. COW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Secy.; PETER MCCOY, Treas.; W. L. COOPER, Eng.

General Office of Company:
Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingston Gold Mining Co., Boulder Co., Colo.; The Puzos Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champie's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned King and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Con. Gold Mining Co., Revenue via Norris, Mont.; and others in course of erection.

The object of this company is to introduce the MacArthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process. If you desire an experimental test communicate with the secretary.

If the results of the test are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties.

The process consists of pulverizing the ore to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubes especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ore for this process is the so-called refractory gold ores, pyrites, hematites, malachites and tellurides. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL, Gen. Mgr. and Secretary.
P. O. Box 926.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$5.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from crumple as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

HOISTING ENGINES FOR MINES

Metallurgy and Ores.

SELBY
SMELTING and LEAD CO.,
416 Montgomery St., San FranciscoGOLD AND SILVER REFINERY
And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF—
BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, Etc., Etc.
ALSO MANUFACTURERS OF

Standard Shot-Gun Cartridges,
Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN
ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Soot flues, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest price. Our Illustrated Catalogue and Assay Tables sent free on application.

Electricity.

Use of Accumulators.

In spite of the obstacles that have beset the path of the accumulator, this much maligned piece of apparatus has gradually advanced until, on the other side of the water at least, it holds a most useful position, not only as an adjunct in the central station, but in other lines as well. In this country, however, litigation has been the chief cause of backwardness, and the accumulator has not been given the same opportunity to prove its usefulness. At the present time, however, the tangle made by the lawyers is gradually being cleared away, and it is fair to presume it will not be long before some of the manufacturers will feel that their positions on patent matters will admit of an aggressive campaign to convince American electricians that they are losers by their failure to make a greater use of the storage cell. When the time comes, doubtless we will be able to see that, despite our claims about the great progress that has been made on this side of the water, we are decidedly behind the times. At least such will be the reader's impression after a perusal of the opinions of the London *Electrical Engineer* on the "Specialization of Accumulators."

Our contemporary feels itself to be in a position to point out that the time is rapidly coming when it will be considered "as loose to speak about or specify an 'accumulator' as it is to specify a 'dynamo.'" To-day, in drawing up specifications for a dynamo, the requirements of a situation are accurately determined, and the dynamo is specified and made—direct or alternating, shunt or compound or overcompounded, with light fields or heavy fields, large airgap or small airgap—according to the conditions for which it is required. "The same specialization of the accumulator has not yet been achieved," says the London *Engineer*, "but it must come."

There seems to be no question but that our contemporary is right in the opinion expressed above. Our foreign cousins make use of the storage battery in a way that leaves no doubt that they at least appreciate its value. And the fact that in England the time is rapidly approaching when the "specialization" of the accumulator will be deemed an advisable procedure on the part of the manufacturers, may be looked upon as a most encouraging sign. The time will come on this side as well, as on the other, when this step of specialization will be a necessity. We have experienced already, like the English, a demand for several types of cells, each specially suited to a particular class of work. The call for portable work is one thing; the call for traction work is another.

We concur, therefore, says the *Western Electrician*, most heartily in the opinion expressed in the article referred to, that "greater attention to this point must prove of advantage to the industry at large."

An Unsolved Problem.

Since in obtaining power from fuel by means of steam engines upward of 90 per cent is wasted, according to Prof. Elihu Thompson, in unused heat, while the power obtainable for use represents scarcely more than 10 per cent of the real value of the fuel under the very best conditions, the question arises whether there may not be discoverable a plan whereby a much larger percent age of the real value of the fuel may be turned to account as electricity, and through the latter as heat, light or power.

This question has at present no answer. The subject has been alive in the minds of our most able engineers and inventors for years, and some have striven hard to find a solution to the problem. Records of scientific discovery have been earnestly ransacked to find some clue, or, as it were, a guiding post to point the way for the uncertain explorer. It now appears that we may be compelled to wait some new discovery, some new adaptation, or some new generalization before the way to the much-desired solution may be found. The effect on the general industrial and economical development in electricity which would follow the discovery of some, not too complex, means for realizing an economy of even 40 or 50 per cent of the energy value of fuel is indeed incalculable.

Then truly would electricity become the almost universal agent in the production as well as the transmission of power. The steam engine would go out of use almost entirely. We should burn our coal not under steam boilers; it would be consumed in electric generators. Our steamships would have their machinery replaced by such genera-

tion, and their propeller would be turned by gigantic electric motors connected with the generators. The speed would be increased so as to still further shorten the time of an ocean voyage. The uses of electricity as a heating agent would be vastly extended, and it goes without saying that our lighting would be accomplished at a much less cost. *Manufacturers' Gazette.*

Electrical Railway Mail Tube.

The postoffice department at Washington has decided to make a practical test on an electrical railway mail tube for transporting mail between New York City and Brooklyn. This railroad is the invention of Mr. A. Bryson, and is operated by the Automatic Dispatch Company, of which G. Mudge is president and Oscar Wheeler secretary. The system contains a miniature trolley line inclosed in a 16-inch square conduit. The mail matter will be placed in carriers of steel wire four feet long and 14 inches square, each pouch containing 3000 letters or an equal bulk of other mail matter. A small electric motor at the end of each gives the car motive-power, and the current is obtained from a wire running between the track. It is said that these cars will run at a speed of 75 miles an hour. Their operation is automatic, so that at either end the clerks will merely need to load and start them. The conduits in which it is proposed to operate the trolley-car are suspended to the framework of the Brooklyn bridge and the elevated road on Adams street in Brooklyn. The frame for the New York end has not yet been determined on. The postmasters of both cities are thoroughly convinced of the practicability of the proposed scheme. Mr. Thos. McGilligot, general manager of the Automatic Dispatch Company, expects to begin work as soon as the bridge trustees have given their consent to the use of the bridge.

As it is at present, the mail traffic between the two cities is badly congested and the New York office daily sends to Brooklyn on an average 55,000 letters and 30,000 circulars and packages, besides many extra pieces from outside points which are rehandled and transferred. The work is at present accomplished by wagons leaving the office every hour, and there are many hours during the day when the trip is made slow and uncertain by frequent blockades and vehicles.—*St. R. R. Gazette.*

The Alternating Current Ampere.

Referring to the definition of the alternating current ampere in the report of the committee of the Board of Trade on electrical standards, *Engineering* says:

"The definition of the strength of an alternating current is made to depend on the square root of the time average of the square of its strength at each instant of its period, which is not, it must be confessed, readily intelligible, but it may, perhaps, be put as follows: The amperage of an alternating current is equal to that of a constant current, when the heating effects of the two currents passing through equivalent resistances are the same. If the resistance is constant and noninductive, the heating effect measures the whole energy expended and is proportional to the square of the current, and when the latter is constant is very easily calculated. If the current is alternating we may divide its period into a convenient number of small parts and consider the current as having a constant but different value throughout each of these parts. If we add all these strengths together and divide by the number of parts, we shall get a mean value of the current, which, however, will prove to be zero if taken through a complete period, as, for each value of current in one direction, there will be an equal value of current in the opposite direction, and taking note of this difference in sign, the average current will be zero. If, however, we regard the heating effect, we shall obtain this by adding together the squares of all the values of the current throughout its period. Dividing this by the number of values, we shall have the mean value of the square of the current, and the square root of this will be equal to the strength of a constant current having the same heating effect. This process is, in short, that of finding the square root of the time average of the square of its strength at each instant of its period."

EFFECT OF ELECTRIC LIGHT ON PLANTS. At a recent meeting of the Manchester association of Engineers, Mr. B. H. Thwaite, referring to the effect of electric light in accelerating the action of plant life, showed the leaves of the *Acacia cophanta*, which were closed while in darkness, when removed into the brilliant beam of the arc light, opened almost magically, the leaves nearest the root being the first to be influenced.

NO. 51 FREMONT STREET, SAN FRANCISCO, CAL.

BUILDERS OF**"Sensible" Horse-Power Hoisting Whims.****(DAVIS PATENT.)****PRICES REDUCED.**

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, on hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake woods at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to places for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and sheaves, 1400 lbs.
 Circulars giving Capacities and Prices furnished on application.

RUPTURE,

PILES and all other diseases positively cured, in from 30 to 60 days, WITHOUT OPERATION OR DETENTION FROM BUSINESS. Also ALL NERVOUS, SKIN, BLOOD PRIVATE AND CHRONIC DISEASES OF BOTH SEXES. SYPHILIS AND URINARY TROUBLES CURED. No charge unless cure is effected. Consultation free. Call or address for pamphlet, DR. PORTERFIELD & LOSEY, 888 Market Street, San Francisco, Cal.

 GEO. H. STRONG

Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED 1860

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, San Francisco.

The Local Coal Trade.

The condition of the coal market and statistics covering the 12 months ending December 31, 1892, as compiled by J. W. Harrison, is as follows:

The consumption of coal during the past year, as compared with the preceding 12 months, shows an apparent falling off of about 300,000 tons, but it must be remembered that dealers commenced this year with excessive stocks in yard, and the statistics of receipts do not include the San Pedro and San Diego importations, which in 1891 amounted to about 161,000 tons. Low prices have ruled throughout the year; in fact, the average quotations have been the lowest known.

Under ordinary circumstances, the very low prices of fuel should have made our manufacturing interests very profitable, but, unfortunately, general business in that line has been below the average. The importers of foreign grades have been the principal sufferers, as there have been losses made on every cargo which has arrived here unsold, notwithstanding charters have been effected at exceptionally low figures from Great Britain and Australia. The market is now recovering somewhat, with every evidence of further strengthening. As this is not a very seductive port for vessels to seek with the present low charter rates for grain, the prospects for any early improvement seems somewhat remote.

The following table of prices will show the monthly fluctuations of foreign coals for "spot" cargoes, the average price being given for each month:

NAME.	Jan.	Feb.	March	April	May	June
Australian (gas).....	\$6.50	\$6.25	\$6.25	\$6.00	\$5.87	\$5.75
English steam.....	6.25	6.25	6.25	6.00	5.87	5.75
Scotch Splint.....	7.00	6.75	6.75	6.50	6.25	6.00
West Hartley.....	7.00	6.75	6.75	6.50	6.25	6.00

NAME.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Australian (gas).....	\$5.75	\$5.87	\$5.87	\$5.12	\$5.25	\$5.37
English steam.....	5.75	5.87	5.87	5.12	5.25	5.37
Scotch Splint.....	6.00	6.25	6.25	6.50	6.75	7.00
West Hartley.....	6.00	6.25	6.25	6.50	6.75	7.00

The various sources from which supplies have been received during the year are as follows:

	1891.	1892.
British Columbia.....	652,457	471,540
Australia.....	321,197	240,940
English and Welsh.....	188,888	201,460
Scotch.....	31,840	20,930
Eastern (Cumberland and Anthracite).....	42,210	34,120
Franklin, Green River and Cedar River.....	178,230	159,850
Carson Hill and South Prairie.....	156,750	202,320
Mount Diablo and Coos Bay.....	50,684	68,140
Japan, etc.....	20,679	4,960
Totals.....	1,702,833	1,402,290

The above figures show a marked falling off in the imports from British Columbia during the past year. The low prices ruling caused a partial suspension of shipments, as they were unable to profitably compete with the prices paid for Australian, Cardiff and Swansea cargoes. The consumption of these two latter grades has very largely increased, they having become very popular with some of the heaviest consumers, who have tested them for the first time this year.

Importers are not so solicitous to make contracts for future delivery as in former years unless they are paid full figures, mainly because this year's experience is very fresh in their memory, and they are less liable to hazard shipments, unless sales are made prior to loading.

Coke—The arrival of foreign coke during the past year was 19,910 tons, being less than one-half the quantity imported (40,974 tons) in 1891.

ALASKA PLACERS.—John P. Lindsay, an Alaska post trader, pilot, salmon canner, etc., is here on a business visit. Mr. Lindsay lives at Chilkat, about 150 miles to the north of Juneau and the same distances from Sitka, where he carries on his various occupations with his partner, John Dalton, the deputy United States Marshal, an old Arizona pioneer and a native of Texas. He says: "When I return I shall take with me a cargo of supplies and an outfit and horses for a big pack train which we intend to establish in the spring. This will be a great thing for the country in the far interior the country along the Yukon to the mines being the principal places benefited. Of course, we are not doing this wholly to benefit those places or entirely for our health. There is a lot of money in it. At present the miners have to do their transportation by boats or rafts on the Yukon. At White Horse rapids they have to land their rafts, pack the goods over the ranges and build another raft to proceed on the journey when they set around to the river again. The Indians do the packing on their backs over the ranges, which costs \$40 for a hundred pounds. Our pack-train will carry from

Chilkat to Mixkaheer, a distance of 250 miles, to a point beyond the rapids. Rafts will then complete the journey to the mines, a total distance of 600 miles. I shall take a lot of horses up with me. There are only five there at present, and they are the pioneers of Alaska, having been taken there by Elades and Dalton, and used in their explorations of the country as far as Mount St. Elias."

Carson Valley Ranchers and Millmen

The *Appeal* says the long and needless war between the Carson Valley ranchers and the Carson river men stands in a fair way of being settled. The proposed basis of compromise is as follows:

The Mill Company and the ranchers are to enter into a stipulation that the mills take a decree for 6,000 inches of water from September 15 each year to June 15 of the following year, and for 5,000 inches from June 15 to July 15 of each year, the ranchers to have all the balance of the water flowing in the river, and from July 15 to September 15 of each year the ranchers to have all of the water flowing naturally in the river, the water to be measured at Cradlebaugh's bridge in a box or gate to be constructed under the joint supervision of the ranchers and millmen. It is understood that 6,000 inches is about the quantity of water that will fill the Mexican ditch at Empire. The ranchers are to have sufficient water for domestic purposes and for watering stock at all seasons of the year without regard to the quantity in the river.

It is believed the mill companies will accept the compromise.

An electric railway system without overhead wires or underground conduits has been brought out by Mr. Wynne, late manager of the Brush Electric Light Co., of London. The main principle of the system is the use of charged sectional contact rails covered by the moving car. These are laid in the roadway parallel to the ordinary track, and successively charged from an underground insulated conductor, but only those contact rails are electrically charged which are actually under or so close to the moving car as to absolutely protect the ordinary traffic of the streets from the possibility of contact with the electricity. The chief engineer of the Electric Construction Co. is said to guarantee the efficient working of a line laid on Mr. Wynne's system.

IDAHO'S OUTPUT.—The Boise National bank for Wells, Fargo & Co. has collected the statistics for Idaho for the year just closed. The figures are as follows: Gold, 1,790,000; silver, \$2,798,000; lead \$2,475,000; total, \$7,063,000. In 1891 the production was: Gold, \$31,500,000; silver, \$565,000; lead, \$4,200,000; copper, \$75,000; total, \$8,996,000, a decrease in the production of \$6,017,000. The decrease was due principally to the fact that many mines are shut down owing to the low price of silver. The Cœur d'Alene strike also caused a decrease in the production. A statement has been prepared showing that it cost the state \$214,159 to suppress the strike in the Cœur d'Alenes.

COAL IN MEXICO.—A vast bed of lignite coal has been discovered but a short distance from the seacoast, a few miles north of Guaymas, Mexico. Senor A. Artigues, who has recently arrived from the scene of the discovery, claims that the coal possesses superior burning qualities for household purposes. A company of Arizona capitalists have organized to operate the mines. It is proposed to ship several hundred tons of the newly-found article to San Diego and Los Angeles to have its qualities thoroughly tested there.

RAILROAD TO ASPHALTO.—The Southern Pacific Company's branch line of railroad, extended from Bakersfield to Asphalto, is finished and will begin operations on the 18th of this month. As there is very little traffic, there will only be one train, which will run three times a week. Asphalto is a small settlement at the asphalt mines, and asphaltum will be the principal freight taken over the new branch line.

HYDRAULIC MINING IN NEVADA.—A carload of twelve-inch iron pipe arrived at Golconda yesterday for Judge Bonfield's placer mines south of that place. It is to be used in bringing water to the placers for use in hydraulic mining.—Silver State, January 9th.

MINING assessments falling delinquent in January amounted to \$280,700, of which Nevada mines want \$270,000 and California mines \$10,000.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISSELL, 650 Market street, Chronicle Building, San Francisco.

Sterling Water Tube Safety Boiler,

Safest, Most Economical and Durable Boiler in the Market. Specially Adapted to Mining Purposes—Being Easily Transported over Mountain Roads.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the wear and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight riffling surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifflings also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrating belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us offer to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

BAY STATE.—Amador Record, Jan. 12: Superintendent Jones of the Bay State mine at Plymouth telegraphed from San Francisco on Saturday last to turn on the water which supplies the mine with power. The Talisman mine, part of the South Spring Hill property, is being bothered somewhat lately with excess of water. The South Spring Hill is, however, looking well in all its parts and turning out the usual amount of bullion. Norman Wheeler, of Plymouth, was in Sutter Creek on Tuesday and visited the Record office. Mr. Wheeler is of the firm of Wheeler, Wild Bros., owners of the Wheeler mine. He reports that the mine is looking fine. They have a shaft sunk 60 feet in a granite formation. At the bottom of the shaft the ledge is six feet in width, which averages on a thorough test of 116 tons over \$5 per ton in free gold; the sulphurets were not valuable. Experienced men think that as the shaft goes deeper and they get below the water level, the ore will improve in value and sulphurets will prove an important item in the output. They are now erecting a live-stamp mill on the property, which is being manufactured by Knight & Co. of Sutter Creek. The machinery is expected to be finished by them this week. Mr. Wheeler hauled a portion of it Tuesday. They are grading and framing the timbers so that when the machinery is all delivered it will take but a short time to erect the mill. It is expected to have the mill in running order not later than the 15th of next month.

TUNNEL.—Amador Ledger, Jan. 14: Contractors Dwyer & Hurley, who have been running a tunnel 150 feet on the Farrell property for the owners, Wise & Seligman, have completed the contract and are now cross-cutting. The water has been lowered in the Hector to the 800-foot level, and in a short time they expect to see the bottom of the shaft a the 1000 foot level, as there are no large openings between those levels. The Kennedy mine made the largest clean-up for December that ever was made in the history of that property. It amounted to \$68,000. At the same rate for the year the mine will have returned the neat sum of \$816,000. At the Wildman, sinking is progressing very rapidly. They are not troubled much with water, and are advancing about 20 feet a week. They are below 900 feet and are going to the 1000-foot, when they will cut stations and resume operations at the mill. The South Eureka are now hulkheading the water on the 500-foot level preparatory to resuming sinking. The hulkhead will be made of three walls of 16-inch timbers set in concrete, the hulkhead being arranged with air and water valves, so that at any time the water can be drawn off. The Newton brothers of Woodbridge have been having some prospecting done on Joe Mason's ranch. The Cox brothers have been doing the work by contract and have struck a ledge of good-paying rock, so they claim. The investigators of the prospect came up Monday to visit the property and arrange for further developments.

Butte.

THE ARMSTRONG MINE.—Oroville Mercury, Jan. 14: In conversation with A. T. Graner, the Mercury learns of important quartz developments at Oregon gulch. The old Armstrong mine, recently sold by himself and L. Lester to Woodland parties, is being developed with every indication of permanency. Some ten or twelve men are at work driving a tunnel in on the lode, and the owners expect to largely increase the force in a short while. Mr. Graner will go to Woodland on Monday to confer with the owners of the mine. If developments are according to expectations, a mill will shortly be erected.

Calaveras.

MILL STARTED.—Calaveras Prospect, Jan. 14: The mill at the Herold mine, near Big Bar, formerly known as the Leavitt mine, was started up last Monday, and operations are being pushed ahead in a lively manner. The mine has been worked by a tunnel following the lead for over 800 feet, and out of which a sufficient amount of ore was taken to keep the mill running for a year to come. The ore is free-milling, easily taken out, and will pay from \$5 to \$10 a ton without the sulphurets, which run from \$1 to \$500 a ton, or averaging \$100 per ton. A Huntington mill is used at present, but it is the intention of the company to put up a ten-stamp mill in the spring.

Mono.

GOLD CAMANT.—Lundv Index, Jan. 14: Yesterday an Indian showed us a pound or so of the rich gold cement so much talked about 35 years ago. It was the genuine stuff, and plumb full of glistening, yellow metal. He was going to Bodie to sell it to Soderling for "fifty" dollars. Every winter the Indians get this wonderfully rich stuff somewhere in this region. The locality of the deposit cannot be many miles away. Legend places it in a deep canyon on the eastern slope of the Sierras, within Mono county, and not far from the summit. It is sure that the Indians know where it is, but they won't divulge the secret.

Nevada.

A PECULIAR CLAY.—Nevada Transcript, Jan. 16: Sam Casper of Truckee, who is at present in this city, brought down with him a sample lot of clay taken from McGlashan's tunnel, near Truckee. He left some of the peculiar-looking substance at the Transcript office, and we have tried it for washing hands and pronounced it an excellent detergent. It looks very

much like the sediment which forms in reservoirs or lakes, and is evidently a sediment deposited from some ancient river or lake, as the layers can be plainly seen. The clay is impalpably fine, there not being any perceptible grit to it, and water readily softens and dissolves it. The deposit is owned by Truckee men. C. F. McGlashan being at the head of the company. It is proposed to incorporate and work the claim, with a view of putting the clay into proper form for sale in the market, both as a toilet and household article.

Napa.

QUICKSILVER.—Calistogan, Jan. 9: During December, 1892, quicksilver from the mines was shipped from Calistoga as follows: Mirabel, 464; Great Western, 412; Sulphur Bank, 113. Total for month, 989.

Placer.

GOLD NEAR SAGE HILL.—Placer Argus, Jan. 14: Considerable excitement was caused at Michigan Bluff, on Monday, when the report reached town that Henry Scheimer, formerly superintendent of the Golden Fleece mine, but who is now working his own mine near Sage Hill, had struck a bonanza in the shape of a large number of "chunks," some of which weighed as high as \$30. The report is that there are plenty more left. Oscar Baggs, one of our young mining experts, went to Last Chance to find the ledge. The rock prospects \$3000 per ton. Mr. Baggs has not returned yet.

Shasta.

HIDDEN TREASURE.—Shasta Courier, Jan. 14: One of the owners of the Hidden Treasure, at Iron mountain, was here this week. Prospects are not as favorable as last week, but they intend to push the tunnel in 100 feet on the ledge, as the mine has produced some very rich ore, and the owners hope that further developments will reveal something permanent. The Levi, or Minnesota, mine below the Hidden Treasure and situated on Spring creek, about five miles from Shasta, promises to develop into a regular bonanza. The ledge has widened out to seven feet and it is all pay rock. The property is owned by Chicago men. They use the Parmelee dry process, and the mill, which has a capacity of about 14 tons, will not start up until next summer, probably. Simoni and Xavier are running a crosscut on their Lower Springs property. George Leivys and John Lord have located a ledge on Kanaka gulch, west of Shasta, that promises well, and we hope the boys will realize a fortune out of the property. Paige and Drury struck some exceedingly rich rock in the tunnel a few days ago. Jim Dawe, who has been down here working his mine this winter, went up to Squaw creek, where he and ten others own a big ledge that promises to develop into a bonanza. A. M. Brewer showed us some gold this week taken from the mine owned by himself and Palmer, adjoining Wm. Crum's mine, the Pacific, and is confident that they will soon strike a pocket. The vicinity of Shasta is fairly teeming with prospectors and placer miners, and there is not an unoccupied cabin within a radius of five miles of Shasta.

Siskiyou.

BLUE GRAVEL.—Yreka Journal, Jan. 18: Murray & Co., who have been sinking a shaft at Greenhorn, about half a mile south of the Lee, Lash & Co. claim, to strike blue gravel, have put in a new steam-engine and pump, so as to keep the claim drained in sinking down. They have reached a depth of over 50 feet, and feel confident of striking the same kind of rich blue gravel found by Lee, Lash & Co. Lee, Lash & Co. received their new pump last Friday, and will soon resume operations, having been obliged to suspend work on account of their old pump being no good. The Ashland Tidings says the Crowsons, father and son, and T. T. Hills, of that place, and Pearson Bros., of Cottage Grove, who have mining properties adjacent over in Siskiyou county, near the Anderson ferry, have consolidated their interests and formed the Pearson Mining Company, which was organized in Ashland last Tuesday, with George Crowson as president, T. E. Hills, secretary and treasurer, and George W. Crowson general manager. The Pearsons have a four-stamp mill at their mine, which will be kept running at present, and the new company has bought the Jacobs five-stamp mill at Henley, and will move it to a point on Klamath river above the ferry and near the mines. Geo. W. Crowson went over to the mines last Friday.

Sonoma.

CINNABAR KING.—Sonoma Tribune, Jan. 12: Recent developments at the Cinnabar King mine, in the Pine Flat belt, are reassuring of the great worth of the ledge. Ed. White, the superintendent of the mine, was in Healdsburg the other day and brought with him some fine specimens of ore. He is confident that wealth is in store for the owners. The vein's depth is far greater than what was anticipated, and its thickness is nearly uniformly 40 feet. There is little doubt now that a furnace and smelter will be purchased by the company soon, and that the mine will be extensively operated.

Trinity.

NEW RIVER.—Blue Lake Advocate, Jan. 10: Mr. George Dean left Blue Lake recently en route to New River. Mr. Dean came down three or four weeks ago, and is going up on a brief visit. He is present superintendent of the Ridgeway mine and the pioneer miner there. New River camp is about a hundred miles from Korbel, 40 miles east of Trinidad, and has an approximate altitude of 5500 feet. The first snow is liable to fall in October, but sometimes does not come until November. It usually is gone before the close of April, though not seldom it lies on the ground until June. The journey to New River is usually accom-

plished on muleback over trails. Residents of that section expect to have highways some day. Just now a wagonroad is in course of construction from Etna to Sawyers Bar, which is expected to afford some relief. "The roughest job I ever undertook, however," remarked Mr. Dean, "was the transportation of two mortars and a rock-breaker from the north fork of Trinity to New River. We hauled them over mountains and across gulches where, so far as appearances went, the foot of man had never trod, and along precipices frightful enough to make even a Blondin turn pale. It cost us \$1800 to haul them 40 miles. I was glad when it was all over." Mr. Dean has unbounded faith in the future of New River. The mines there, he says, are passing through the successive experiences of all paying mining properties, and that there are quantities of gold in the New River claims he now doubts. The placer mines on Pony creek, he suspects, have been pretty well worked out, but he says there is good mining property on both forks of the Salmon. Work on the Ridgeway mine will go on, and, considering the depth reached, encouraging developments will be in the near future expected. The distance from the top of the shaft, or tunnel, to the bottom is 400 feet, the first 217 feet being on an incline and the last 183 feet perpendicular.

ENTRAPPAISA.—Trinity Journal, Jan. 14: J. L. Day informs us that the Enterprise mine, in the East Fork district, is looking very well. This week a foot ledge of good rock was struck in the Enterprise, and a 4-foot ledge of milling ore in the Lone Jack. There are over 100 tons of rich rock in sight. The 10-stamp mill belonging to the company was started up Thursday and will run night and day. The Enterprise has been the best paying mine in the district and we are glad to hear of the new strike. C. C. Shattuck was in town from Canyon creek this week and informs us that he has struck the ledge in the Buck Ranch mine, for which he has been running a tunnel the past season. The ledge where cut is five feet wide and of good quality of ore. An upraise will be run to the upper tunnel and when this is completed a good deal of ore can be taken out. It will take about 60 days to run the upraise. There are two Huntington mills on this property which have a capacity of about 20 tons a day. Jas. Mullane was in town this week on land business, and informs us that the outlook for New River for the next season is most encouraging; in fact, he considers the prospects of the camp as good as they ever were. Quite a sum of money has already come out of New River and at this time it can hardly be said that enough development work has been done to thoroughly determine the character of the mines. The people of this county have always had a good deal of faith in the permanency of that camp. Wm. Vollmers was in from Trinity Center this week, and informs us that work on the Cinnabar mines has been shut down for the winter, but it is expected work will be resumed in the spring on a larger scale than ever. There is no question but that Cinnabar contains one of the largest and most valuable deposits of quicksilver in the State. The two principal companies are the Altona and Integral. If litigation ceases, the camp will progress with giant strides the coming season.

Tuolumne.

POCKETS.—Sonoma Democrat, Jan. 14: Charles Saunders and Charles Penrose, who are working a pocket claim on the Batten ranch, have within the past two weeks taken out over \$1000 worth of gold. The prospects for a larger find are very encouraging. Quite a number of strikes have taken place lately in our pocket mines. The lucky finders are not saying much, yet it is well-nigh impossible for a pocket-miner to conceal his good luck.

NEVADA.

Washoe District.

CON. CALIFORNIA AND VIRGINIA.—Virginia Chronicle, Jan. 14: 1500 level.—We continue running water through the old east crosscut from the south drift, 30 feet south from the shaft station, which has reached the old slope timbers, and is working down through them to the 1650 level. From the end of the main south drift, or the connection with our sill-floor stopes, we have completed filling with waste rock the openings connecting with the 1650 level. We are in full possession of the stopes on this level and have ventilating air passing through every part of it. Are repairing the ore chute and ladderway leading to the ninth floor. It will take five days to complete this work, and we will then resume ore extraction from this level. There is very little gas escaping through the Con. Va. shaft. 1600 level.—Are repairing the main south drift and the east crosscut leading therefrom to the upraise connection with the 1500 level, north drift. 1650 level.—Have continued making necessary repairs to the drifts on the sill floors of this level. Have extracted from the old stopes, eight floors up in the upraise No. 6 carried up from the main northwest drift, and raised to the surface 124 tons of ore; average car assay value, \$30.72 per ton.

OPHIA.—1465 level.—The upraise started on the sill floor, on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground, 101 feet below the sill floor of this level, has been carried up 8 feet; total height, 74 feet, continuing in porphyry with quartz.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 20 feet; total length, 463 feet; continuing in porphyry and clay showing lines of quartz.

UNION CON.—900 level.—The joint Union C. n. and Sierra Nevada west drift has been extended

during the week 26 feet; total length west of joint shaft, 2821 feet. The face is in porphyry and streaks of clay.

UTAH.—340 level.—West crosscut No. 3 from the north drift from west crosscut No. 2, at a point 195 feet in from its mouth has been extended 12 feet; total length 76 feet. The face of this crosscut is in quartzite and clay formation, with eight inches of water flowing therefrom.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 32 feet; total length, 568 feet; face in soft porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 26 feet; total distance west of shaft 2821 feet; face in porphyry and streaks of quartz.

GOULD & COAR.—200 level.—During the past week, west crosscut No. 5, started 435 feet from main west drift, has been advanced 14 feet; total length, 242 feet; face in porphyry and stringers of quartz. All work has been discontinued in west crosscut No. 6. Sinto tunnel level. The joint north drift with Savage Co. has been advanced 24 feet; total length, 816 feet; face in porphyry.

BEST & BELCHER.—200 level.—All work on this level during the past week has been timbering and repairing. 900 level.—West crosscut No. 3 has been extended 20 feet through hard porphyry; total length, 69 feet.

EAST BEST & BELCHER AND NORTH GOULD & COAR.—Drifting is being continued, passing through quartz that looks well.

ANDES.—On the 420 level are retimbering and repairing main north drift. Resumed work in face of north drift run from east crosscut No. 1, north, and advanced the drift 12 feet; total, 31 feet; face all in quartz of very low assay value.

HALE & NOBACROSS.—We continue retimbering main shaft above the 600 level. Main Incline.—Are making the necessary repairs, and are retimbering incline above the 1800 level. 1800 level.—West crosscut No. 1 from the main south drift was advanced 25 feet; total length, 235 feet; face in porphyry with small bunches of quartz. No. 3 west crosscut from the main north drift was advanced 17 feet; total length, 235 feet; face in hard porphyry. West crosscut No. 4 from main north drift was advanced 20 feet; total length, 94 feet; face in porphyry with some small bunches of quartz.

CHOLLAR.—The north drift from the south line, 550 level, is out 95 feet; face in quartz and porphyry. Are repairing north compartment in the main shaft, 930 level. The north drift from the east crosscut, 160 feet south of north line, 930 level, is out 90 feet; face in porphyry and clay with streaks of quartz through it.

POROSI.—The south drift from top of raise, 1100 level, is out 22 feet; face in quartz that assays from \$30 to \$35. Are grading and enlarging the connection between the Potosi winze and the northwest drift, 1800 level Ward shaft. Extracted and sent to the mill the past week 372 tons and 1500 pounds of ore from the 550, 930, 1100 and 1150 levels. Milled during the week 380 tons; on hand at mill, 81 tons 550 pounds. Average battery assays, \$32.49. Average car sample assays, \$31.15.

WARD SHAFT.—There has been no work done on the 1800 level of the Alpha and Exchequer during the week. Have been engaged in placing pressure pipe in the shaft. The west crosscut from the northwest drift, 300 feet south of north line of Billion, 1800 level, is out 185 feet; face in low grade quartz and porphyry. Are grading and enlarging the connection between the Potosi winze and northwest drift, 1800 level.

OCCIDENTAL.—The main north drift, 750 level, has been extended 14 feet; total distance from No. 1 winze station, 590 feet; face continues in low-grade quartz. Have completed the station for No. 2 winze in south drift and have resumed working at that point. East crosscut No. 2 in Zadir drift, Sinto tunnel level, has been advanced 23 feet; total length, 143 feet. The face is in porphyry and quartz.

BULLION.—East crosscut, 160 feet north of top of raise, from east crosscut 320 feet south of north line, 1300 level, is out 47 feet; the face is in quartz and porphyry. The west crosscut from the northwest drift, 300 feet south of north line, 1800 level of Ward shaft, is out 185 feet; face in low-grade quartz and porphyry.

EXCHAUER.—There has been no work done on the 1800 level during the week. Have been engaged in placing pressure pipe in the Ward shaft.

ALPHA.—There has been no work done on the 1800 level during the week. Have been engaged in placing pressure pipe in the Ward shaft.

KENTUCK.—Work done in the mine from the 6th and 7th floors above the east crosscut on the 160 level. We are extracting 10 tons of ore per day of the average value of \$33 per ton, as per car sample.

NEW YORK.—The west crosscut, 55 feet north of shaft, 850 level, is out 77 feet. It has cut over 40 feet of quartz which occasionally shows spots of ore, but as a whole is low grade. We continue to extract 10 cars of ore per day from the 700 stopes, car samples averaging \$40. Shipped to Washoe mill the past week 165 tons 337 pounds of ore; milled during the week 165 tons 337 pounds of ore; on hand at mill, 60 tons; average battery assays, \$44.55; average car sample assays, \$42.33.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 6 feet; total length, 29 feet; the face is in hard porphyry.

WORK EXPANDING IN THE CON. CAL. & VA.—Enterprise, Jan. 13: Eighteen men were yesterday added to the working force of the Con. Virginia mine. That means an increase of \$72 a day in local earnings, and about \$2250 a month

added to the pay-roll. This is good work that everybody will be glad to see continued. Superintendent Lyman of the Con. Cal. & Va. writes to San Francisco under date of the 11th instant as follows: "I intend to go to the 1100 within a week or two and try to recover our air-pipe and track that we had to abandon at the time of the fire. We cannot work there at present, and in a very short time all the drifts will close from ground pressure. On the 1500 level the stope is cooling off gradually. During our abandonment of the 1500 stope the ore chute and gangway through which we send the ore from the stopes above and hoist timbers up, crushed and closed so that it will take five or six days to make necessary repairs to use them again. When this work is done we will resume ore extraction from that point." This is good news. The extraction of ore will gradually increase, and work in the mine be expanded until it employs as many men and puts as much money into circulation as it did prior to the gas troubles.

TWO HUNDRED DOLLAR ORE.—Robert Mahanny, an old and reliable miner, has made a valuable strike in the Apex claim on Mount Davidson. He has a tunnel which is in some distance in the mountain, and which has recently disclosed a ledge of rich ore. Assays from the ore made a few days ago yield \$200 a ton. The ledge of ore in the face is eight feet in width, and promises a mighty good thing for Mr. Mahanny. He will continue the development of his claim, and is highly sanguine of opening up a good mine.

A SEMI-LOCAL INDUSTRY.—The Dayton Dredging Company is a hard combination to down. It is about to renew operations on a new basis that is expected to bring better results than in the past. Mr. Rae, Jr., the superintendent of the dredge at Dayton, yesterday received a telegram from the secretary of the company at New York stating that the company is preparing to expend \$40,000 to change the machinery on the dredge and institute improved methods in the work. The new departure will be begun shortly. The Dredge Company has spent something like \$100,000 in its dredging enterprise. The money has come in from the outside, and the enterprise has therefore been a good thing for Dayton. There are millions of dollars in the bottom of the Carson river, and everybody who has watched the perseverance of the Dredging Company hopes it will get there eventually.

Cottonwood District.

NICKEL AND COBALT.—*New Era*, Jan. 14: The group of nickel and cobalt mines, owned by John D. Sullivan, in Cottonwood, is reported to be a very valuable property. Those who have examined the claims speak very highly of their worth. The district in which they are located, for three miles square, is said to be highly mineralized with nickel and cobalt.

Tuscarora District.

TWO RUNNING.—*Silver State*, Jan. 10: V. M. Nelson is back from Tuscarora. He is one of the many miners let out of employment in the camp by the closing down of mines. The Navajo and a gold mine, which is owned by W. J. Urton and others, are the only mines which have not closed down. About 25 men are employed in the former and 12 in the latter. Hard times prevail, and the outlook for the old camp is very gloomy.

NAVAJO.—*Tuscarora Times-Review*, Jan. 13: The stopes above the 350-foot level are looking about the same.

BELLE ISLE.—The stopes above the 250-foot level still show good ore making north.

NORTH BELLE ISLE.—The stopes above the north 300-foot level are yielding a little very good ore, as is also the stope above the south 400, No. 1. Have discontinued No. 3 stope.

Pioche District.

BULLIONVILLE.—*Pioche Record*, Jan. 12: The work of reducing the large tailing pits at Bullionville, by the Bullionville M. & R. Co., has about settled into a steady business, and the work is rapidly advancing and expanding. A successful run of the chloridizing furnace ended three days ago, when the whole cooling floor was piled high with tailings ready for the leaching tanks, which, with present tank capacity, it will take ten days yet to dispose of. The White & Howell roaster in which the chloridizing is done can easily put through from 40 to 45 tons a day, or more, the chlorinations running to 70 per cent and upward. The leaching is fully up to the chlorinations if time is given, but giving the necessary time curtails the capacity of the tanks, as now operated, and less than 20 tons a day can be disposed of. All modern appliances for the economical and rapid handling of the ore are provided, and the necessary repairs are reduced to a minimum.

ANOTHER will now be made to increase the working capacity of the tanks by adding a pump to each and using the leaching liquor over and over again before precipitating. If successful, this will double the present work. In addition, larger and larger tanks will be added to the early spring. At present the leaching is done by the aid of steam, and steam and compressed air are used to force the sulphides through the filtering press. The sulphides when dried are marketed with the Omaha & Grant Smelting Co., at Omaha, and not converted into metallic bars, as was done here some years ago. A reverberatory furnace of ten tons capacity per day is in course of construction at the east end of the works. The slimes in the tailing pits, always carrying well in silver, will be chloridized here, as in the White & Howell roaster the draft is too great and carries too large a proportion of the slimes into the dust chambers. A set of large Krom rolls is also being placed, and will soon be in readiness for work, when custom ore from this and surrounding

districts will be treated at the works. This branch of the business is one much needed in this section and will provide a market for larger quantities of ores, which at present prices will not bear the cost of transportation to Salt Lake markets. W. S. Godbe, manager of the company, with his characteristic energy and push, has brought matters to their present state of perfection, and will not rest until the whole plant is as complete and perfect in every possible detail as modern science can make it. The result of this will be many years of steady business for the old town of Bullionville, for without any outside ores to reduce it is estimated that ten years will be required to work up the tailings at Bullionville and Dry valley, nine miles north, which the company already own.

THE YUBA MINE.—The prospecting and general development work in this mine is showing up some shipping ore on the upraise from the 1300 level, east. A 20-inch vein of heavy lead, free-smelting ore shows up on the west end of the stope, which the company will proceed to ship, though the price of silver is so low. In the east end of the stope the ore vein has widened considerably, showing two feet of 60-ounce ore, which, however, it will not pay to ship at this time. In the levels above, large quantities of similar-grade ore is uncovered, which can be reduced profitably only at some local plant. As soon as the Bullionville Mfg. & Rdn. Co. is ready for the reduction of general ores, regular shipments from this mine will be made to that place.

ARIZONA.

COPPER OUTPUT.—*Phoenix Herald*, Jan. 14: The past year has been one of great prosperity to the O. D. Co. under the able management of Mr. Walker. The output has steadily risen until the year 1892, when the total amount of copper bullion produced reached the enormous figures of 8,019,059 pounds more than was ever produced before in a single year, and the output for the next 12 months promises a still greater showing. The projected railroad from Bowie to Globe seems to be an assured fact, and the knowledge of fast communication with the outside world has caused new life in the camp, and before the year draws to a close it is safe to surmise that the population of Globe will be greatly increased with the iron horse steaming up, our future is indeed bright, and it is safe to presume that this will be one of the most prosperous camps in Arizona, and Gila county will take front rank.

BRIGHT PROSPECTS.—*Gazette*, Jan. 12: Captain John McCassey returned last night from the Harqua Hala, where he has been doing his annual assessment work. He brought in some rich silver specimens from the Leland Stanford, and some rich gold ore from the bottom of the shaft of the same mine. The assessment was done on the Leland Stanford, owned by Geo. H. N. Luhrs, Capt. R. G. Andre and Capt. McCassey. The mine shows a 4-foot vein of carbonate of lead, rich in silver and gold. In the center of the carbonates a vein of quartz ten inches wide occurs in which gold, visible to the naked eye, as large as peas is found. The Golden Chariot, owned by Julian Piercy and Capt. McCassey, has very rich gold ore in the bottom. The Selig mine is in good gold ore. At the bottom of the shaft a vein of quartz has occurred that shows up well in gold. The Selig is owned by Mrs. G. H. N. Luhrs, John McCassey and the heirs of the late Tobias Selig. The clean-up at the Hnbard & Bowers mill amounted to \$73,000 for the month of December. The old Harris mill in the town of Harrisburg is being put in repair to work the old Socorro mine. W. C. Davis and Alex. McKay of Tucson have wonderfully rich gold mines in the new district of Golden, in Maricopa county, 25 miles westerly from the Vulture mine. The ore is ferruginous quartz in granite. The veins are massive. An open cut has been run on the California for 40 feet, and \$50 free gold ore permeates the vein. The Harcuvar Copper Co. uses a diamond drill, and when the captain left it was down 581 feet, with fine prospects of copper. The Vulture mill is idle for want of water, but Mr. Farish is still working the mine and is taking out good ore.

IDAHO.

THE BRYANT & CHAPMAN MILL.—*Statesman*, Jan. 15: F. C. Bryant has decided upon a site for the Bryant & Chapman mill. It is to be placed near the More creek bridge, on the Idaho City road, about 14 miles from this city. Yesterday, Mr. Chapman went East to purchase some new machinery, and the owners expect to have the mill running by March 1st. Mr. Bryant will leave to day for Idaho City to secure the necessary water-rights. This mill is the one which was expected would be established in this city. Mr. Bryant says that the parties who owned the water-rights would not make such arrangements as he considered reasonable, and it was decided to go elsewhere. The mill consists of ten stamps, but will be increased in working capacity in the spring.

OREGON.

STILL IN ABEYANCE.—*Baker City Democrat*, Jan. 15: Notwithstanding that reports have been current on the streets that a reorganization of the Virtue Mining, Milling and Development Company had been effected and that all things had been definitely arranged for the starting up of the old property at once, such is not the case. However, parties are attempting to bring about such a result and have paid off a number of claims against the old concern at a discount. But there yet remain the claims of Parke, Lacy & Co., of Portland, and Basche & Company, to be satisfactorily adjusted before a wheel moves. When such an adjustment occurs it will look like the parties mean business.

DRILL TAPPING.—This forenoon Messrs. T. F.

Foster and Chas. Rebnhn, who, together with Mr. M. Hoff, are the owners of the Bsrber mine in the White Swan district, a parallel vein with the Laura, will leave the city with all necessary camp and mining equipments for a season of development work on the property, which presents very flattering prospects. They contemplate running a tunnel 200 feet in length.

LUCKY BOY AGAIN BONNEN.—The Lucky Boy mine, in the Bonanza district, has again been bonded, and it seems with a good prospect of a future sale taking place. The parties bonding the property are Messrs. L. O. Nelson, of this city, and a Mr. McCormick, a capitalist of Chicago, and under the terms of the bond \$2000 is to be expended in development work, operations to commence at once. Mr. John Jenkins, one of the owners of the mine, is in the city.

MINE JUMPING.—There were quite a number of mining claims jumped and relocated in the Telocaset mining district, by miners from Baker City and elsewhere, New Year's day. The Dierks mine was relocated under the name of the White Rose by J. L. B. Vial of Baker City; the Bonanza, under the name of the Monumental, by some miner from the Cracker creek country. There were also five or six claims located on the ore body in the Government Gulch country, by Baker City people. C. F. Hinckley relocated F. C. Borden's Jim Blaine claim, under the name of the Black Maria. Numerous other abandoned claims were located by different parties. It is hoped the coming season will be one of activity among the quartz ledges on Powder river.

MONTANA.

AROUND BUTTE.—*Inter-Mountain*, Jan. 14: Bar silver shipments showed some signs of improvement for the commencement of the new year. The Alice is now the principal silver-producer of the district, and to mining men this means a great deal, because the Alice is the oldest mine on the Rainbow lead. The Alice shipment this week consisted of 30 bars, which weighed 2806 pounds, the estimated value of the shipment being \$44,896. The Lexington Co. shipped 12 bars, valued at \$27,136. During the year 1892, 738 bars were shipped via the American express of an estimated value of \$1,180,300.

MONTANA DIVIDENDS.—The dividends paid by the mining companies of Montana during the year 1892 were as follows:

Bald Butte.....	\$ 20,000
Bannister.....	6,000
Bi-Metallic.....	200,000
Elkhorn.....	362,500
Granite Mountain.....	500,000
Hedra Con.....	180,000
Helena and Frisco.....	20,000
Iron Mountain.....	135,000
Jay Hawk.....	33,375
Moulton.....	30,000
Pandora.....	3,000
Parrot.....	216,000
Rocky Fork Coal Co.....	100,000

Total.....\$1,805,375

THE EUREKA.—The Eureka mine in Jefferson county, about 20 miles from Boulder, is owned by C. P. Groves. This is a gold proposition, with a shaft about 24 feet in depth. The lead is said to be between eight and nine feet in width and the ore assays all the way from \$18 to \$40 a ton.

THE FREDDIE LEE.—Jim Wardner has for some time past been steadily shipping out ore, and now he is beginning to ship in machinery, says the *Nelson Miner*. This week he brought up from across the line an engine and boiler, which he intends to use to break up the ore of the Freddie Lee into pieces of a size suitable for sacking.

THE ELLA.—Drifting on the lead is still in progress at the Ella, and the leasers are feeling more confident each day that they have uncovered the famous ledge from which thousands of dollars' worth of ore was taken from the Travana, which adjoins the Ella on the west. The first shipment will be made next Monday, after which regular shipments will be made.

NOTES.—The Odin mine, in Dublin gulch, has been started up by Messrs. Kelly & Co. This property is known to contain very rich ore, but the trouble hitherto experienced in the working of it has been the large quantity of water encountered in the shaft. Several leasers have "gone broke" for this reason alone. The Speculator is under lease to Frank Case & Co., and is being worked on the lower level only. At the Parrot mine a new cable is being placed on one side, while the hoisting is being done on the other. The Nora mine, the property of W. A. Clark, has been bonded by the Boston & Montana Co. Stopping is in progress at the Oro Plata and some good ore is being obtained. The Amador is still working under lease to Messrs. Williams, Ralph & Co. The Young America Mining Co. is a new incorporation, organized by Indiana and Montana parties to work the Young America mine, in Jefferson county. The property is said to be a promising one, and the management is confident that development will prove the property to be valuable.

UTAH.

GOLD.—*Salt Lake Tribune*, Jan. 14: George Goss has just returned from the gold-fields in southern Utah, says the *Salt Lake Tribune*, and tells an interesting story of his experience in that gold-laden district. He went down from Green River along the west slope of the Henry mountains to Dandy Crossing, 25 miles south of which place he has placer claims on the Colorado. Speaking of his trip, he said to a reporter: "This is my second trip down in that country, and I know it thoroughly. There is plenty of gold there. That much is certain. But the only impediment is raising water on the bars. It is a capitalist's country; not a poor

man's. It will take lots of pumping machinery to reach the gold and work it profitably. With the proper machinery, any number of bars all along the Colorado will produce paying gold. It does not come in nuggets, but is fine, though not too fine to be treated. The Henry Mountain district is the coming mining country. In my opinion, all the gold found on the Colorado has washed down from the Henry mountains. Every gulch leading from the mountains is lined with gold, but it is impossible to get a sufficient water supply there, the spring freshets being inadequate. The only way that these placers could be worked to any extent is by storing water in reservoirs. But there are two large mines up near Mount Ellen, one of which has been bonded for \$40,000, and the bondsmen will take it, for others stand ready to buy it for \$50,000. The mine is working a mill, and the ore is rich and plentiful. It is only 25 miles from the junction of Colorado river and Alceve creek to good coal mines. They are between the river and Henry mountains, and I believe that, with the placing of big mills in that district, Henry Mountain will become one of the best gold-producing districts in the country." Notwithstanding reports that the San Juan country has but little gold in it, miners are flocking there, and the belief is that the placers are rich and that the reports that they are not have originated from disgruntled men. The *Salt Lake Herald* says of the Green River gold: The passenger office of the Rio Grande Western received the following telegram from Green River station last evening: "Five miles from Green River station, down Green river, parties have just located a placer claim that has every appearance of being rich. Surface pannings show from 75 to 100 colors. There is indication of doing better as bedrock is approached. North of the placer claim is a mineral spring boiling from the bed of the river, and gas can be seen bubbling up from the bed of the river all the way across the stream. The water indicates iron, salt, soda, magnesia. Across the river, and nearly two miles from the mineral spring, is a spring of pure crude petroleum which runs about five gallons an hour. Mr. Meyer, of Ogden, an experienced miner, who has recently patented a machine with which he claims he can save 75 per cent of the finest gold, has been panning on bars down Green river to-day, and claims he will bring his machine here and go to work. He was on his way to the San Juan gold-fields. People who are on their way down Green River to the San Juan gold-fields are stopping to prospect. Intense excitement prevails.

LEACHING PLANT.—*Park Record*, Jan. 14: This week the *Record* man made inquiries concerning the proposed new leaching plant for the Ontario Company and learned that the enterprise was a sure go provided the silver market did not go to pieces before the plans and specification as to cost were prepared and acted upon. Mr. Chambers proposes to know just what the mill, completed and ready for work, is going to cost before the undertaking is started. The grade and grounds for the building were surveyed and mapped out this week, and the cost of the foundation will soon be known. The present intention is to build a mill of much greater capacity than the one now in operation. It will be fitted out with leaching-vats and the Russell process used to reduce the ores. Work will be commenced as soon as the plans and specifications have been drafted and accepted. The mill will be first-class in all its appointments, and, as stated in last week's *Record*, will be first used on the old Ontario tailings dams; and after they are cleaned up, the mill will be started up on Ontario ore. At this writing it is not definitely known just when work will be commenced, though it will probably not be for several weeks, as it will take fully that length of time to prepare plans and figures on the cost of the construction. The signs of the times point very strongly to renewed activity and a large increase in facilities on the part of the Ontario Company, and the rumor floating about several weeks ago to the effect that the company was considering the feasibility of doubling its capacity, is beginning to assume shape, and there is little doubt that with silver at 90 or 95 cents per ounce, such a condition of affairs would come to pass.

THE DALY WEST.—The Daly West will increase its force early next week, and unless the writer is laboring under a wrong impression, will soon fall into line as an active producer and dividend-payer. In a conversation with Supt. J. J. Daly, who was in the camp Tuesday and Wednesday of this week looking after matters about the mine, the *Record* man was informed that the property had not been closed down—the underground force had been laid off that repairs and improvements might be made in the shaft and about the premises, but he thought he would be ready to increase the force about the first of next week.

STRIKE IN THE CALIFORNIA TUNNEL.—There has been a decided improvement in the vein being worked by LeCompte, Rosscamp and others in the California tunnel, and the indications at the present time are that with proper management, the property can be made to pay handsome returns. The *Record* has described the vein in this tunnel several times and spoken of its possibilities, and when informed this week that a new body of high-grade ore had been encountered in the bottom of a 70-foot incline run below the tunnel level, it became interested and sent a representative to look at the strike and make a truthful report as to the exact condition of affairs. The vein was found to be all that was represented, and gives every indication of becoming a paying mine under proper management. The entire tunnel shows ore of a low grade, while the face of the winze 70 feet from the tunnel level shows a five-foot body of ore of a good concentrating grade, and rightly handled will produce pay ore. The truth is that the property gives every indica-

tion of developing into a mine that will pay a handsome profit.

THE STEEL GROUP LEASED.—The above group of claims, seven in number, has been spoken of by the *Record* several times as a most promising prospect. In fact, the property is a very promising one, and it is to be hoped that under the administration of Messrs. Oscar Allison, C. E. Berg and August Lind, who have just secured a two-years' lease thereon, will develop into a bonanza. Mr. Steel has gone just as far as he could single-handed and alone, and not wishing the ground to lie idle, has given a two-years' lease on the same at a royalty of 25 per cent. Active operations will be commenced Monday next.

CAMP CROSSCUTS.—The Crescent mill was started up yesterday to run through a lot of Richardson's lease ore. Ore was bailed at a great disadvantage this week. There was too much snow in the cautions to use wagons and just enough below to make the use of sleighs aggravating and use up stock. W. H. Crockett claims to have cut a large vein of low-grade ore in a piece of ground he is working just below the Glencoe. Jerry Richardson reduced the force at his works during the present week, laying off about ten men. The force at the Marsac mill was also reduced by the discharge of an equal number.

Market Reports.

Financial and Commercial Review.

SAN FRANCISCO, Jan. 19, 1893.

SILVER.—The same stagnant conditions that have ruled in the silver market for some time are still to be chronicled. Quotations in both London and New York have been almost without change for the week, and no activity has been manifested. The recent closing-down of the Rico Aspen Consolidated group of mines in Colorado, caused a small sensation. The Colorado *San* published interviews with prominent mining men, all of whom declare that the step is the result of the depreciation of silver and high wages paid to miners. Another recent feature of moment is the following resolution, by the New York Metal Exchange, at a special meeting called January 9th for that purpose: "Resolved, That we demand the prompt repeal of the laws under which authority is given for the purchase of silver by the U. S. Government, and that the president and secretary and two members of the Exchange be, and are hereby appointed a special committee to deliver a copy of this preamble and resolutions to the President of the U. S. and to the Senators and Representatives in Congress."

IRON.—A dispatch from New York of date Jan. 16th reads: "At the New York Metal Exchange to day very little else was talked about than the sharp advance in the price of tin. It is alleged that several prominent operators in the local market have entered into an agreement to create a 'corner,' There was a fear on the part of the bears that some of the bear traders who had orders to fill would be seriously embarrassed, and that the noted tin corner of a few years ago would be repeated. There was also talk of a movement by the bears to counteract the 'corner,' and the market continued in an unsettled condition." The reported corner and the advance have had no appreciable effect on the market here.

PIG IRON.—Reports from Philadelphia are to the effect that pig iron is beginning to move in large volume, and on the whole, the indications seem to favor a fair degree of activity, but at distinct concessions from the figures ruling before the holidays.

STEEL BILLETS.—A lower tone pervades the eastern market. Buyers are very indifferent, while sellers are increasingly anxious.

THE LOCAL MARKETS.—There are no features to the local metal markets of this city.

--	--	---	---	--	--	--	---	---	---	--	------------------------------------	--	--	--	---	---	---	---	--	---	---

The following brief list by telegraph, for Jan. 10, will appear more complete on receipt of mail advices:

California—Jonathan Edwards, Sanger, furniture; Augustin J. Galindo, Concord, wagon-jack; Christopher Grattan, Stockton, braks for harvesters; Alexander Janson, San Francisco, lounge; Charles W. Lockman, Crescent City, ventilator; E. A. Rix, San Francisco, clutch for rock-drilling machine; Alfred F. McMillan and T. Gormley, Beicola, gang-plow; H. P. Nielson, Alameda, automatic releasing device; E. S. Rayburn and C. A. Bell, San Jose, hand-truck; Peter V. Shandoney, Sacramento, draft-equalizer; James Scott, Bethany, tug clip for hames; John P. Summons and E. J. Holmes, San Francisco, adjustable rock-crusher; A. Livingston, San Francisco, can-body forming machine; E. J. Molara, San Francisco, camera shutter.

Washington—Ernest Bernini, Tacoma, egg-cutter. Oregon—Herbert A. Corlies, St. Helena, self-hoisting floodgate; Thomas A. McFarland, Portland, sketching device.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ELEVATOR HATCHWAY ATTACHMENT.—Chas. M. Prevear, S. F. No. 489,755. Dated Jan. 10, 1893. This attachment for elevator hatchways is especially applicable for sidewalk elevators. It consists in certain details of mechanism whereby the hatchway is opened by the rising of the elevator, and closed and locked automatically as the elevator sinks below the sidewalk.

BORER FOR WALKS.—James E. Chapman, San Jose, No. 489,792. Dated Jan. 10, 1893. This is a new article of manufacture called by the inventor a "horder corrh and base." Its object is to provide a permanent corrh or horder for garden and other walks or paths and to surround beds and inclosures of any description. The idea is to provide a permanent corrh or border having a horizontal base extending outwardly from the path or walk, of which it forms the border, and the sections of which it

is made are corrugated so as to divert irrigation water outwardly from the path and directly into the beds where it is to be used.

CAN-LACQUERING MACHINE.—R. D. Hume, Gold Beach, Oregon. No. 489,903. Dated Jan. 10, 1893. This is an apparatus which is adapted to apply lacquer to the exterior surfaces of cans containing hermetically sealed goods, the lacquer being applied after the cans are filled and sealed, for the purpose of giving the proper finish to them. The patent covers certain details of construction in the machine.

DETONATING COMPOUND.—Samuel Rodgers, S. F., assignor to the American Cap Co. No. 489,761. Dated Jan. 10, 1893. This is a detonating compound which is specially applicable for use in caps to be employed for exploding charges of powder.

ORE CONCENTRATOR.—Geo. Johnston, S. F. No. 489,744. Dated Jan. 10, 1893. This is a traveling-belt concentrator, and the invention consists in the novel improvements in the pulp and water-distributors. The objects of the invention are, first, to distribute the pulp upon the belt in narrow channels in the direction of its travel, and as close to it as possible, leaving wide spaces upon the belt between the discharge courses, where the sulphurets can remain undisturbed by any fall of water or sand, and pass up to the clear water at the head of the belt, the sands at the same time passing down in the same channels without obstruction to the foot of the belt; second, to deposit the clear water in the same channels on the belt, from a platform or board having narrow slots in the line of said channels, and so arranged as to discharge the water without pressure and with the least possible splash. By the ordinary method the pulp is generally discharged from an apron across the front of the pulpbbox, usually in a shallow, continuous stream, and also in a number of streams some distance from each other across the width of the belt. It is to avoid the resultant disturbance of the sand and sulphurets that these improved pulp and water-distributors have been devised. By the peculiar construction of this inventor's pulpbbox, he drops the pulp, not indiscriminately across the belt, but only in specified definite places through the narrow slots. It is thereby deposited in narrow channels on the belt, and being close to its surface it falls without much splash or disturbance. A large portion of the surface of the belt is undisturbed by the fall of the pulp, and the sulphurets working to each side of the line or channels in which they were deposited form in parallel rows in the spaces between said lines or channels and ascend to the clear water at the head of the table. The sand particles have no splash to obstruct their downward flow, but pass down the same channels or lines to the foot of the board. The clear water is similarly applied. It falls gently without pressure and with as little splash as possible and directly into or upon the same channels or lines upon which the pulp was deposited, said lines or channels being bare by the time the water discharges are reached, occasioned by the working of the sulphurets into the parallel side-rows and the downward flow of the sand. The slots in the pulpbbox and water-frame are arranged in line to effect this deposit of the pulp and the water in the same lines or channels. As a

result of this construction, about two-thirds of the belt is undisturbed by any splash of sand or water, the capacity of the belt is increased and cleaner work is done.

The Mining Share Market.

Trade in mining stocks continues dull with a decline in several securities. The depression in the stock market is very hard on the brokers, and there is no present prospect of a very radical change. The project to pump out the mines on the Comstock and renew deep mining is hoped for up on the lode, but all hands must join. On Monday pumping operations in the Gold Hill group of mines were suspended. The sinking pumps in the Crown Point are being hauled up above the water line, and the main pumps that will be left in position are to be painted to preserve them when the water reaches a point above where they are stationed. The project for consolidated pumping along the entire lode has not yet been consummated, and should a favorable understanding be arrived at, it will take several months to arrange details. Hence the Gold Hill association does not feel justified in continuing the work at a loss without deriving any material benefit.

At the annual meeting of the stockholders of the Brunswick Mining Company the following officers were elected: J. R. Robinson, president; J. J. Halpin, vice-president, and T. H. Chandler, H. W. Philbrook and W. C. Wallace, directors. H. R. Lounsbury was elected treasurer and general manager, W. C. Hawley, superintendent, and J. Siadtfield Jr. secretary.

At the annual meeting of the stockholders of the Bullion Mining Company about 90,000 shares were represented and the following officers elected for the ensuing year: Thomas Cole, president; Thomas Anderson, vice-president, and Charles Hirschfeld, C. W. Kellogg and J. H. Souther, directors. R. R. Grayson was re-elected secretary and A. C. Hamilton superintendent. The secretary's financial statement showed a credit of \$8760.54.

The stockholders of the Sierra Nevada Silver Mining Company have re-elected the following officers: Charles H. Fish, president; Charles Hirschfeld, v. c. president, and Herman Zadig, George W. Cope and A. K. P. Harmon, directors. E. L. Parker was re-elected secretary and A. J. McDonnell superintendent. The secretary's report showed a credit of \$9603.17.

Local securities were quiet this morning.

SAN JACINTO ESTATE, LIMITED,
Office of General Manager,
P. O. Address, South Riveride, San Bernardino Co., Cal.
CALICO, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodburn" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
I am, my Dear Sirs, Yours faithfully,
S. HARRIS, Manager.

To Prevent Floods in the Valleys.

The Drainage and Reclamation Convention in session at Sacramento decided to recommend the planning and construction as an entirety of a complete and unpretentious system of drainage and reclamation. It appears from the report of its engineers: First—That there exists an area of 800,000 acres of submerged lands in the Sacramento valley partially reclaimed by the existing works constructed and maintained against adverse natural conditions under increasing burdens of cost by reason of the absence of a comprehensive system of reclamation embracing the entire area. Second—That the construction of such a complete and comprehensive system of reclamation, to be thoroughly effective, is possible at a cost per acre of less than the cost per acre of the partial reclamation already effected, and that the engineering data already exists for the planning of such a system. The engineers have reported that the rivers of the Sacramento valley, in their present condition, do not afford sufficient flood-drainage capacity, and building a bank protection alone will not prevent the annually recurring disasters nor afford reasonable protection to the valley lands. Recognizing this fact the committee reports that aside from the works required to accomplish local protection, others of general benefit are necessary to facilitate and hasten the flood discharge to the bay and to control the surplus water. The treatment of the flood-carrying capacity of natural watercourses must be increased, and the works, to accomplish this end, must be supplemented by drainage channels of sufficient capacity to control and receive the surplus water.

The opinion is expressed by the engineers that, aside from the work of channel treatment for many years, the property benefited should be prepared to incur within the period of five years an expenditure of \$8,000,000 to \$10,000,000 for the work and general benefit, and that this expenditure is justified and advisable, and will afford reasonable protection to all the lands of the Sacramento valley. All of this forms a pretty "big contract," but the engineers are doubtless right in recommending a comprehensive scheme. Small attempts here and there are costly and effect little good. By systematic general plans everybody will be benefited. The engineers say that levees alone will not answer the purpose, which is a very evident proposition. In the early days of this State the valleys were flooded as now. As the land became settled levees were built and the waters no longer had the chance to spread laterally. They must therefore rise in flood times, and this season were higher than ever before. Mining debris, natural wash and agricultural operations have all contributed to shoaling the river system to a greater or less extent. But, as stated, there were floods before hydraulic mining or plowing was carried on along the borders of the tributaries of our great rivers. Reclamation schemes have kept the water back from certain tracts and thrown it upon others. The waters cannot spread laterally, as before the levees were built, and when they rise and break through great damage is done.

The physical conditions are such that an expensive, comprehensive plan must be adopted, which will give the flood waters a chance to reach the ocean without obstruction. Obannels must be deepened and straightened. The water rushes from the mountains and strikes the level of the valley, where its speed is slackened and it is confined between narrow banks. At certain seasons floods must result unless means are devised which will permit the storm

water to drain off more rapidly. It is with this object in view that a comprehensive plan of drainage and reclamation is suggested.

THE Senate Committee on Mines and Mining will report favorably an important measure introduced by Sena-

CONSTANT POTENTIAL DYNAMO OR GENERATOR.

THE DARDANELLES MINE ELECTRIC PUMP.

tor Ford, providing that hydraulic mining may be carried on wherever it can be done without injury to navigable streams. The same course will be taken with Ford's bill creating a board of debris commissioners and appropriating \$20,000 to construct dams and restraining works, provided that Congress appropriates at least the same amount.

THE famous Conception silver mine at Atorco, State of San Luis Potosi, Mexico, is on fire, and one work after another is collapsing. The fire broke out in the main shaft, which collapsed, causing a heavy loss of life. Thirteen corpses have already been recovered. The destruction to property and the paralyzation of work will entail financial loss of over \$1,000,000.

By an explosion in the Fortschritt mine at Dux, Bohemia, on the 23d, 80 miners lost their lives.

Electric Power in Drift Mining.

The electric power and lighting-plant installed by the Electrical Engineering Co. of San Francisco for the Dardanelles mine, Placer county, Cal., consists of a 25-horse power Keith electric generator, a 6-horse power electric pump, a 6-horse power electric hoist and 50 incandescent lamps. The pump and hoist are operated by Keith motors. The electric plant was substituted for the cable transmission previously used.

The Dardanelles is a prominent gravel mine, on one of the ancient river-beds, which, before the antidebris decisions, was a large producer of gold by the hydraulic method. It is now, however, worked by the drift method. This latter necessitates the use of a tunnel one-half mile long through the rim rock. At the inner end of this tunnel is an incline of 330 feet, up which all the water and gravel from the mine must be raised before passing out to the mill through the tunnel.

The power to run the pump and hoist used before the electric plant was installed was conveyed to them through the tunnel by the use of a continuously-running wire cable one mile long. The expense of keeping this cable system in working order was enormous when renewals, delays and damages were taken into account. Two cables costing \$1400 were worn out each year, and many delays were caused by the stranding of the cable, which necessitated frequent repairs and the consequent delays.

By the substitution of power transmission by electricity, the expense has been reduced to the minimum, so that the initial expenditure of power has been decreased fully three-quarters.

This is an important matter, especially as during four months of each year steampower must be used, because the waterpower belonging to the mine, and used during eight months, is not then available. Three cords of wood were used each day to run the cable, but less than one cord is necessary by the electric system, even when the 25 electric lights in the tunnel and incline are continually lighted. The further saving of wear and tear is of much importance. No additional men to those otherwise employed in the mill and mine are engaged in operating the electric plant.

The mine is owned by Gen. Jo Hamilton of Auburn, and the superintendent is H. F. Calenberg at Forest Hill. We illustrate the generator and pump in use, and will shortly do the same with the hoist.

DISCOVERY OF GOLD IN CALIFORNIA. — On Tuesday evening Mr. John S. Hittell delivered a lecture before the Pioneer Society in this city on "Marshall's Gold Discovery." "To-day," said the lecturer, "is the forty-fifth anniversary of the greatest event in the history of our State, the day when the gold deposits of the Sierra Nevada were discovered at Coloma by James H. Marshall. It was the 24th of January, 1848, that caused the great migrations of 1849 and of subsequent years to California, and that made the admission of our State into the Union on September 9, 1850." He explained fully his reasons for fixing the date of Marshall's discovery as January 24, basing his authority upon the entries in the diaries of Henry W. Bigler, Azariah Smith and Captain Sutter, although Marshall himself had variously given the date as January 18, 19 or 20. He spoke of the annual celebrations of the admission of the State into the Union, and gave his reasons why the anniversary of the more important event of the gold discovery had never been celebrated.

Comment.

The legislature has before it a bill providing for the appointment of a board of examining engineers to license engineers of portable and stationary engines. It does seem rather odd, on consideration, that the fact of an engine being afloat makes it necessary to have a man over it who understands his business, while one ashore can be run by a Chinaman if the owner pleases. Every engine on a steamboat, for business or pleasure, comes under U. S. regulations, and the engineer must be licensed. Stationary engines in cities or towns, or portable ones on farms or fields, may be run by Tom, Dick or Harry without license or supervision of any kind. No inquiry is made as to his qualifications or whether he knows the first principles about steam or steam engines. As long as he can stop and start the machine and read the gauge, he is supposed to be all right. At any rate, this kind of engineer prevails everywhere. The only wonder is there are not more frequent accidents. Should the proposed bill become a law, engineers would have to pass some kind of examination before being allowed to run engines, which would result in a better class of men to handle stationary and portable engines.

A notable decision was rendered this week by the Superior Court of Alameda county. In a suit over the Oakland water-front, not only the Oakland Water Front Co., but all the claimants were thrown out, the decision being that the title is absolutely vested in the State without power to grant it away, and no previous judgments of the State courts are of effect. The opinion of the court is based on the recent U. S. Supreme Court decision in the Chicago water front case, where it was held that the State could not convey to private ownership. The court says:

It would seem to be that the town of Oakland, being a creature of the State and a part of its government, was selected by the State as the trustee of this property. The town has no greater power of disposition over the property than had the State itself. Since the State could not dispose of the property in gross, its trustee, the town, could not do so, neither could it ratify or confirm any such attempted disposition of it.

A formal motion for a nonsuit was then made and granted by the court. A. A. Moore, for the Water Front Company, then made a statement and moved for a stay of 60 days in which to prepare an appeal, and this was also granted. The Oakland Mole, Long Wharf, the Peraltastreet freight slips, the Broadway creek-route wharf, the narrow-gauge wharf, all go with the decision and are now on State property. Everybody who held title through the Water Front Company and the Carpenter grant also found themselves without title. This includes the Pacific Iron and Nail Works, at the foot of Market street; the Oakland Gas, Light and Heat Company, at the foot of

Grove street; Remillard Brick Company, at the foot of Clay street; the Merritt property, now under lease from the Garcelon estate by the Puget Sound Lumber Company, and Taylor & Co., lumber dealers, covering a block of water front between Washington and Clay streets, and all of the recent wildcat claims that have been made during the recent water front excitement. The decision is a sweeping one and affects the water front all along the whole bay shore. It will go a long way toward settling the title and be a great thing for commercial and manufacturing enterprises needing a water-frontage. Should the decision be sustained, which appears probable in view of the U. S. Supreme Court decision, the water front of Oakland will come under the supervision of the State Harbor Commission, just as the San Francisco water front is. At all events, the land bordering on the harbor can be utilized, and the railroad can no longer control it or the city.

The Future of the Comstock.

Those most directly interested in the future of the Comstock lode—the residents of the vicinity—are seriously considering the situation up there, recognizing the fact that unless there is some change in present conditions, active operations in mining properties must practically cease. At a meeting of the Washoe Club there were present J. B. Overton of the Virginia and Gold Hill Water Company, Mining Superintendents J. H. Kinkead, A. J. McDonel, P. Kervin, E. D. Boyle, J. R. Ryan, D. B. Lyman, S. L. Jones and C. C. Thomas of the Comstock Tunnel Company. Those present organized themselves into a committee of the whole by the appointment of D. B. Lyman as president and James H. Kinkead, secretary.

After organization the outlook of the mining interests of the Comstock was discussed pro and con. It was the universal opinion that urgent steps should be taken immediately to revive the drooping prosperity of the lode. It was thought a reduction might be made in freights and fares and railroad charges for transporting ores; also in the price of milling and the furnishing of water to the mining properties. Subcommittees were appointed to discuss ways and means to secure various reductions needed to insure future prosperity in mining and milling operations. The Mining Stock Association has already pointed out, in a very vigorous manner, sundry reforms that should be made, but as many of these conflict with the moneyed interests, but little attention has been paid to them. Now, however, that the gentlemen mentioned have taken the matter up, some good should result. They know of the abuses that exist, and should see some remedy. High charges for freight and water must cease, and at once. The mill ring operations should also be stopped. The public have got out of conceit with the mining share market, since the mines and the public have been "milked" for years. Now it has come home to the residents of the Comstock that they must give some assistance themselves toward reform, or else they will be let severely alone and must work out their own salvation.

It is rather late in the day to begin, since the abuses have existed for many years and have been constantly protested against by investors. If the people on the lode take up the idea of reforms with a firm hand and without fear, they may put a different face on affairs; but if they content themselves with passing resolutions and do not carry them out, the Comstock will fall into the same decadence as other silver camps in Nevada.

A Proposed State Debris Commission.

Senator Ford of Sierra county and Assemblyman Thomas of Nevada county have introduced bills providing for the appointment of a debris commission to consist of three civil engineers at a salary of \$250 per month, whenever any board of engineers of the United States Government shall be appointed with power to adopt plans and specifications for the construction of works for the impounding of mining debris, the commissioners to consult and advise with the board of engineers and to examine and pass upon the merits of such work, and shall determine by vote whether or not such works are sufficient to protect the navigable waters of the State. The bill appropriates \$250,000 to be used in the construction of works for the restraining or impounding of mining debris in California. It is provided, however, that no warrant shall be drawn against the sum appropriated until the Federal Government shall have appropriated at least an equal amount for like purpose. The term of office of the debris commissioners shall be four years from the date of their appointment, and before taking office each commissioner shall give the sum of \$50,000 for the faithful discharge of his duties.

The object of this bill is to create a State Commission to cooperate with the Government Commission of Engineers in constructing debris dams to keep back the debris now

in the rivers. It will be remembered that the debris bill now pending in Congress says, "That for the purpose of securing harmony of action or expenditures on the work to be done by the United States and the State of California respectively, the former in its plans for the improvement and protection of the navigable streams and to prevent the depositing of mining debris or other materials within the same; and the latter (United States) in its plans authorized by law for reclamation, drainage and protection of its lands, the said commission is empowered to consult thereon with a Commission of engineers of said State if authorized by the State for such purpose," etc. The Congressional bill also provides for future appropriations (without specifying any sum) to build at such points above the head of navigation on the Sacramento and San Joaquin rivers, or the main tributaries, such dams or settling reservoirs, canals, locks, or other works as will keep the debris from coming into the navigable streams. Under the Ford and Thomas bill, the two boards could consult and carry out joint plans each controlling its own expenditures. If the antidebris people are wise they will study their best interests by joining hands in this movement. No money will be spent unless the Government spends a like amount. If no Government appropriations are made for the purpose then the State money is not touched. The dams are not intended for miners to dump their debris into, but to hold back what is in the rivers now. The Congressional bill provides for the mining dams which will prevent any more coming in hereafter. Both sides to the debris controversy can properly support this measure.

The Miners' Association and the Caminetti Bill.

The executive committee of the State Miners' Association has been subjected to some criticism because it asked Senator Felton to have consideration of the Caminetti bill deferred, just as it was about to pass the Senate. In fact, in another day it would have passed both houses and become a law. There was good and sufficient reason, however, for asking for this delay, since in its present form, as amended lately, the bill is obnoxious to the hydraulic miners of the State, for whose benefit it is supposed to be drawn. Most of them would prefer no bill at all rather than this one as it is.

After Congressman Caminetti made the original draft of his bill, it was very materially altered to meet certain contingencies which arose. The miners' representatives in Washington were obliged to concede many points to which they had objected, in the interests of harmony, and to conciliate their opponents. They had to take the best they could get, and that best was the Caminetti bill as it passed the House. When it went to the Senate for consideration, Senator Felton inserted sundry amendments, among which was the word "must" instead of "may" in Section 9, which compelled every hydraulic miner, whether then legally working or not, to file a petition for permission to mine; to surrender to the commission the right and privilege of selecting the method of restraining the debris; and to pay three per cent of the gross output to the United States, even if already mining by permission of the courts.

When this amended bill was considered by the State Miners' Convention in January, it was indorsed, with exceptions, by the following resolution:

Resolved, That the State Miners' Association of California approve of the Caminetti bill, with the amendments proposed by Senator Felton, and recommend the interest of the mining industry of California the passage of that bill, with the amendments; but we further recommend that all reasonable efforts be made to secure an appropriation of \$450,000 for the purpose of the construction of the dams provided for in said act; and we recommend that the word "must" contained in section 9, as proposed by the amendment of Senator Felton, be rejected, and the word "may," as contained in the original bill be restored, or that there be added to the bill the following proviso: "Provided, that this act shall not be so construed as to prohibit the carrying on of any mining operations, prior to the construction of said dams, which can be conducted without material injury to the navigable streams of the State or lands adjacent to said streams."

These proposed amendments were submitted to Senator Felton and Mr. Caminetti while they were here in the city. When, however, the matter came up in the Senate no attention was paid to these requests, no modification was made, and the Senate Committee passed favorably on Mr. Felton's amendments without protest being made as far as the executive committee in this city can learn.

Just at that time, however, ex-Congressman C. P. Berry of Sutter county appeared in Washington in behalf of certain antidebris men of the Sacramento valley, and succeeded in having added to the already objectionable bill a penalty clause, which reads as follows:

"Any person or persons, company or corporation, their agents or employees, who shall mine by hydraulic process in violation of the provisions of this act, shall be punished by a fine of not exceeding \$5000, or by imprisonment not exceeding one year, or by both such fine and imprisonment, in the discretion of the court."

No protest appears to have been made against this sweeping penalty clause, nor any modification suggested by the senators or representatives from this State. When the executive committee of the Miners' Association heard of it, they telegraphed to Senator Felton asking him to have the clause so modified as to exclude at least those

mines now legally working and doing no damage. He replied that he would submit the proposition to the senators, but expressed no opinion. The executive committee of the association then decided to send a representative to Washington to secure, if possible, an amendment to the penal clause to make it apply only to mines which do damage to the rivers and which are interdicted by the courts. The association is short of funds and before the money could be collected to send any one to Washington, it was learned that the bill was about to pass as it stood. The executive committee therefore telegraphed at once to Senator Felton asking him to defer consideration of the bill until the miners' representative could get there and explain the miners' views.

As stated, the Miners' Association has been criticized for this action, because it had already indorsed the bill, and the State Legislature had also indorsed it and asked for its passage. But it will be seen from what is said above, that the indorsement of the Miners' Convention and of the legislature were both before the addition of the sweeping penal clause suggested by Mr. Berry. Telegraphic dispatches from Washington give the intimation that both Senator Felton and Mr. Caminetti are annoyed at the interference and delay and think it endangers the bill at this time. Be that as it may, the miners do not want the bill as it stands.

The fact is the miners do not ask or expect that the penal clause shall be cut out. If the word "must" in Section 9, is to remain, as appears probable, the penal clause is a logical sequence, and cannot be avoided. The miners of the State, and their association, strenuously object to Mr. Berry's penal clause adopted by the Committee of the Senate unless there is an amendment which omits mines not doing injury or damage to the rivers. They are anxious that provision should be made so that the Act shall not be so construed as to prohibit the carrying on of any mining operations prior to the construction of the proposed dams which can be conducted without material injury to the navigable streams or adjacent lands.

If the Senate will not agree to this just and simple proposal, the miners would at least like the operation of the penal clause to be suspended to some specified date when the commission shall have been organized and shall have made its examinations and plans, and be prepared to grant licenses to hydraulic miners. Under the present amendments, many miners now working legally and by permission of the courts (or at least without interference) would have to close down until the commission had prepared its plans and was ready to act on the petitions provided by the bills. This would apply to both large and small mines. Most of the restraining works now constructed have been inspected by the courts or antidebris agents and pronounced satisfactory. Unless the penal clause excepts such claims, they must shut down for a time (and that indefinite) after all the expense and trouble they have had to comply with the law.

The miners generally were prepared to accept the amendments offered by Senator Felton, with the exceptions noted in these resolutions adopted at their convention; but the broadness of this proposed penal clause, without reservation of any kind, is decidedly objectionable to the miners, since it practically puts those doing work legally in the position of offenders against the law. The Commission would take a year, and perhaps two years, to make the required examinations and formulate a general plan, and meantime everybody must wait. It is not asked that those not now working be omitted from the penal provision, but only that the mines now legally working be permitted to continue operations. There is nothing at all unreasonable in this request. The miners do not ask for any illegal mining to go on, but they do think that such mines as are doing no damage to the streams, and are impounding their debris, should not be compelled to quit work pending the action of the Commission. Judge Niles Searles has gone to Washington to present these points on behalf of the miners of California. If the necessary delay results in these modifications being adopted in the bill, it will be a good thing for the hydraulic-mining industry. If, however, it results, practically, in defeating the bill as it stands at present, why then, even that, in the opinion of many, may be a good thing for the hydraulic-mining industry of California.

THE Blue Jacket mine and mill in Elko county, Nevada, are advertised to be sold by the sheriff for a judgment of \$16,322.89. This property belonged to the estate of millionaire Blythe of San Francisco, over which there was a three-year lawsuit.

THE owners of the Hustler hydraulic mine (a mile east of Cherokee) were each fined \$100 for illegal hydraulic mining last week. The tailings from this mine flow into Shady creek.

THE wall shaft in a colliery at Pontypridd, near Aberdare, Wales, collapsed on Monday, and a number of miners were killed.

Coast Industrial Notes.

THE starch factory at Petaluma is nearly completed and in a few weeks will be ready for operations.

STEPS are being taken to put up a cannery at Visalia, Tulare county, and have it ready for operation by next June.

It is reported that new coalfields have been found in two localities 50 and 90 miles northeast of Flagstaff, A. T., and companies have been formed to work the six-foot veins.

THE old worn-out electric-lighting plant at Berkeley has been replaced by Mr. Osborne by an entirely new one with a guaranteed capacity of sixty-five arc lights of 2000 candle power each. Sixty new lamps will replace the present ones.

BADLAM Bros., of San Francisco, have completed their contract for a Peerless gas plant for the United States Government, and the arsenal and reservation buildings and grounds at Benicia are now brilliantly illuminated. The works are a success.

THE Session-Vandercook Company in Oakland, has begun placing poles in position on which to string the electric wires, preparatory to converting its Highland Park road into an electric line. The work of changing the line will be prosecuted with all haste.

OWING to an overstock, disagreements and competition, the members of the Lumber Dealers' Association in Los Angeles have fallen out. The price list has been suspended and every lumber dealer is for himself. Prices took a tumble on Tuesday, and all the dealers are cutting and underbidding each other.

A MEETING of the citizens of Fresno was held Tuesday to consider the Monterey and Fresno railroad project. Considerable interest was shown in the scheme, and \$20,000 of the \$75,000 asked by the projectors of the road was subscribed. A committee on subscription was appointed to solicit the remainder.

WORK on the long-distance telephone connecting Fresno and San Francisco commenced January 18th. This enterprise has been in contemplation some time, but its consummation is promised sooner than was expected. Provision will be made for local service through the thickly settled portion of the country through which the line will pass.

At a meeting of the Oakland Board of Public Works Tuesday the new schoolhouses which are about to be erected in Oakland were discussed. It was resolved that in the erection of the schoolhouses sandstone must be used for the foundation and other portions of the buildings. The clerk of the board was instructed to advertise for bids for furnishing the sandstone.

THIS session of Congress is expected to set apart a sufficient amount of money to enable the building of several structures at the Mare Island Navy Yard, for which plans have already been made, for the housing of a fine lot of tools that have been received for use in iron-shipbuilding. As soon as these tools are set up, the yard will be in a fair way of being properly equipped for this class of work.

AN act to provide for the establishment and maintenance of a training-ship for the instruction of the boys of California in nautical matters has been recommended by the Chamber of Commerce for passage by the legislature. The act calls for the State of California to appropriate the sum of \$100,000 therefor, and the authorizing of the Governor to procure from the Government a ship of suitable size and tonnage for the accommodation of 230 boys.

THERE is a probability that the new Board of Supervisors will be asked to fix new rates for the electric light companies in this city. The claim is made that the board has the same power over the electric light companies as it has over the gas and water corporations, and can regulate rates in the same way. Complaints charge that an electric light trust has been formed in this city, and that the rates are becoming too exorbitant and should be cut down by the supervisors.

DURING the year 1892 from the depot at Placerville, El Dorado county, there was shipped 5,113,655 pounds. One hundred and twenty-two cars, of 20,000 pounds each, and including 62 refrigerators, were loaded and dispatched with green fruit, without transshipment, to Eastern markets. There were, also, of dried fruits 7 carloads. Of wine grapes, 11 carloads. Of lumber, a large increase, 36 carloads. Of slate, for roofing, 60 carloads. Of miscellaneous fruits, in various quantities, 30 carloads.

A BILL of considerable importance has been introduced in the legislature by Raw, of El Dorado county, adding a section to the exercise of the right of eminent domain. It adds canals, ditches, flumes, aqueducts and pipes for supplying water for operating machinery for the purpose of generating electricity for the supplying of mines, quarries, railroads, tramways, mills and factories with electrical power, and also for supplying electricity to light mines, quarries, mills, factories and incorporated cities.

At the annual meeting of the board of directors of the Omnibus Cable Co., it was decided to increase the company's capital stock from 20,000 shares of the value of \$2,000,000 to 25,000 shares of the value of \$2,500,000. The increase of capital is for the purpose of paying for the North Beach and Mission line, purchased some time ago, and to form a consolidation with that line. It is said that should the new storage-hattery car prove successful, the purchased road, the track of which is not in very good condition, will be reconstructed very soon, making it one of the finest cross-town roads in town.

H. A. McCRAVEY, of the Lakeport *Avalanche*, Lake county, says: "We have been needing a railroad for a long time now, and I think we are about to get it. Three different companies have been figuring to run a road from either Pieta or Hopland, on the Donahue line, to Lakeport, via Highland Springs. The proposition has been for us as citizens to raise \$50,000 by subscriptions and they would build the road. The matter has been receiving our

attention for some little time. We have got \$30,000 raised, and there is no doubt that we will secure the remainder. The road will be about 25 miles long and will cost in round figures about \$350,000 besides the subsidy. It will be an electric road and will admirably suit the needs of the people. The line will go through Big Valley, one of the richest sections of northern California, a region of fine farms and orchards, and there will be much produce of this kind to carry out.

WORK has been commenced in Los Angeles on a large five-story brick building for the Cudahy Packing Co. buildings. When completed they will cover an acre of ground and will cost about \$150,000. The full capacity of the factory will be 500 hogs and 150 cattle per day, and when running in full force it will employ at least 200 men. It is estimated that the tributary territory south of Bakersfield now pays out annually for Eastern hog products nearly a million and a half dollars.

WORK on two of the tunnels between Santa Margarita and the town of San Luis Obispo is making good progress. The first tunnel south of Santa Margarita, which is the longest of the seven, being 3616.5 feet long, is now being bored at both ends. A day and a night force is at work and 430 feet of the tunnel is already completed. The work progresses at the rate of ten feet a day, so that it is calculated that it will be finished in 316 days from the time the first shovelful of dirt was moved. On the next tunnel only a day force is now at work.

R. C. McPHERSON, an oil expert, visited the Livermore (Alameda Co.) gas well this week, and is satisfied that there is a large body of oil to be found by boring. He could only estimate the necessary depth, as much would depend on the pressure of the body of gas and the chemical character of the surface penetrated. Some years ago an artesian well company bored down about 100 feet and found indications of asphaltum. Mr. Fowler states that the spring is in perfect line with the strata that intersects the coal mines that J. B. Treadwell is developing about ten miles from Livermore.

THE franchise for an electric railroad on Twelfth street, Oakland, is about to be utilized. The ties are now being laid on the street and work will be commenced at once. The original franchise was for a cable road, but permission was subsequently given to build an electric road. The line running to East Oakland along Twelfth street is about to be converted into an electric road in order to save it from ruin, and it is generally believed that the Grossmeyer franchise on Twelfth street west of Broadway has been purchased by the Southern Pacific Company, who will use it in connection with their East Oakland road, running through cars.

CLOSELY following on the recommendation of San Pedro as a site for the Government harbor comes the news that the Southern Pacific Company will soon begin work on an important improvement on its San Pedro line. The long trestle which crosses the Wilmington slough, between the two towns of Wilmington and San Pedro, is to be replaced by a solid embankment. Work will be commenced at once at filling up the trestle with stone and soil, and will be continued until the pile work is supplanted by a more solid foundation for tracks. The growing traffic of that branch and the age of the timbers in the trestle call for substantial improvement.

THE directors of the California Improvement Company are considering an important change, which will be made in the Oakland and Alameda street railway, now being equipped with electricity. One end of the road is at Seventh and Broadway, in Oakland, and after passing through Alameda the road terminates at Twenty-third avenue, in East Oakland. The directors will ask for a franchise through Oakland to connect the two ends, and cars will run around the circuit continuously in both directions. It has not been decided yet whether to make the road double track, but that will probably be done.

A MEETING of the Saratoga Improvement Company has been held to discuss the question of raising a subsidy for an electric road between San Jose and Saratoga, Santa Clara county. O. W. Wooska and G. Henry, of San Jose, offered to build the road providing local residents contributed \$50,000. The total cost is estimated at \$250,000 and the running expenses for the first year at \$45,000. It is thought no difficulty will be experienced in raising the required amount. Passenger trains will be run every hour, the fare to be 35 cents for the round trip and 25 cents per single trip. The road will ultimately reach Congress Springs and Los Gatos.

THE Builders' Exchange of Oakland has passed a resolution declaring that the best interests of the city demand that at least one practical mechanic shall be a member of the Board of Public Works. A request is therefore made that a competent builder be appointed when the first vacancy shall occur. The exchange announced that they will not support any candidate for Mayor who will not consent to make such an appointment should he be elected. Unless the builders are a very strong body politically, there is little chance of their desire being granted. Such positions are usually given to politicians, without much reference to their knowledge.

ARTICLES of incorporation of the Monterey and Fresno R. R. Co. have been filed with the county clerk of Fresno county. The articles state that the road is to pass through the counties of Monterey, San Benito and Fresno, and its length is to be about 150 miles. The principle office is to be in Fresno. A telegraph line is to be operated in connection with the road. The term of incorporation is 50 years. The capital is \$3,000,000, divided in 30,000 shares \$100 each. Of this amount \$150,000 is subscribed and 10 per cent paid up. J. C. White was elected treasurer of the company. Following are the directors for the first year: A. W. Jones of Kansas city, C. C. Walter of Fresno, Alex. Gordon of Fresno, H. A. Green of Monterey, W. C. Hill of Salinas, Wm. Palmatag of Hollister, Thomas Flint of Hollister. Work on the survey will begin at once, and it is thought that it can be finished in three or four months. Then the work of grading and building the

road is to begin. As soon as a few other arrangements shall be completed a mass meeting of the citizens of Fresno will be called to take vigorous action. It is considered now that the road will be pushed till Fresno is united with Monterey by rail. It is said that all arrangements have been made for selling the bonds of the road. The bonus which the counties have subscribed is not to be paid till 30 days after the road shall be in running order and in actual operation.

REPRESENTATIVE CAMINETTI of California has introduced in Congress a resolution directing the Secretary of War to cause to be made, under the supervision of the Chief of Engineers of the United States army, examinations or surveys, or both, of the navigable waters of the river system tributary to the bay of San Francisco, with the view to permanent improvement for the purposes of commerce and navigation, by means of levees or otherwise, so as to obtain the following depth: At low water, nine-foot depth to the city of Stockton, three feet to Hill's Ferry, seven feet to the city of Sacramento, three feet to a point near Chico, 30 inches to McIntosh Landing, 20 inches to Red Bluff, 30 inches to the city of Marysville, and to report the result thereof to Congress on or before November 1, 1893, with complete plans and details of the same, together with estimates of the cost.

INDICATIONS point to the establishment of a new railroad through the Santa Clara valley, to be owned and operated by the San Francisco and Santa Cruz Railroad Company. The company was originally formed for the purpose of building a railroad between Ravenswood and Gilroy, one from San Jose to Alviso, and one from San Jose to Saratoga. The first named road will be operated under the name of the San Francisco and Santa Clara Railroad, and the last two under the name of the San Francisco and San Jose Transportation Company. It is intended to connect Ravenswood with San Francisco by steamers. One of the promoters of the new road says that the details have all been arranged and that work will commence in a short time. He adds that the necessary equipments of the road have been contracted for and that some of the material is now on hand. Part of the road is expected to be in running order on May 1st next.

THE report of E. C. Prieber, Viticultural Commissioner of Napa county, has just been issued from the State Printing Office. When the last census was taken, Napa county reported 18,299 acres in vines. The present report shows a decrease to 16,651 acres. Of the 507 vineyards in the valley, 244 report phylloxera. The disease is now spread over 2246 acres. Whenever resistants have not been used, the death of the vines appears to be only a question of a short time. The reports of wine stock show that there are 5,000,000 gallons now in the valley. The commissioner stated that no remedy to prevent the spread of the disease had been discovered, and at only two of the entire number of vineyards visited was the disease being specially treated. As a rule, vineyardists have come to the conclusion that any special treatment is useless. The report states that some of the cellars are overstocked with wine of the vintage of four years ago, and prices are considerably below the figure desired.

W. J. EDBROOKE, supervising architect of the U. S. Treasury Department is inspecting the Government buildings on this coast. He will prepare the plans for the new postoffice in this city. He and Mr. Erygia accompanied by Lyman Bridges, J. C. Martin, Charles S. Chadbourne, Colonel W. D. Sanborn, Rudolph Herrold Jr. and Messrs. Duggan and Brady, visited Knowles & Hosmer's quarries at Raymond, Fresno county. Other quarries had been previously inspected with a view of ascertaining the quality of stone, ease of access and facility of transportation, and the Raymond Granite Company's quarry appears to offer the best inducements. The stone in sight promises well for blocks of any size being procured. Mr. Erygia says that there is one ledge alone 200 feet long and 10x10 square without a defect. Another ledge 230 feet long, 14 feet thick and 26 feet wide was noticed, so that blocks of any size or shape can be hewn from these quarries if necessary. In laying foundations, especially on ground of the nature of the postoffice site, huge blocks are often required.

At the last meeting of the Academy of Science there was a discussion on the subject of natural gas in the Sacramento valley. It was opened by Mr. Watts, a field agent of the State Mining Bureau. In his work for the bureau he has recently been at work in the Sacramento valley, and has visited and examined those wells which produce gas. As yet none of them produce in quantities to be practically useful, but there have been no wells bored specially for gas, and none of them have been properly cased to keep water out and allow the gas to rise to the surface freely. Gas is always found with a strong brine, almost as salt as sea water, and in wells which flow through brine the gas bubbles up and can be ignited, and there are a few instances of it exploding in wells when brought in contact with a flame. The gas is found in each of the groups of cretaceous rocks. It is accompanied by a strong smell of petroleum and in one or two places petroleum was found oozing from the rocks. The small quantity of gas found in the Sacramento valley is of a good quality for heating purposes, but no estimate of the pressure can be made until wells are drilled and cased to exclude water.

THE new association of the Alaska salmon cannerys includes about 36 canneries. The temporary combination of last year proved to be so practicable and was so successful that the majority of the large canners desire to continue the plan. Out of the thirty-six Alaska canneries all were shut down but nine, and these produced all the canned salmon which was demanded at a much less cost than had it been produced by all the canneries with the usual commercial competition. The intention of the combination is to can all of the salmon required by the market with economy and to control the output, so as not to flood the market and cause a low price to follow. The plan is to allow each canner a pro rata of stock on the basis of the

productive capacity and the apparent profit his cannery or canneries would have in the event of a good price ruling. At present the principal concerns on the outside are the Alaska Improvement Company and the Behring Sea Packing Company. They were not in the combination of last year, but reaped a benefit from the operations of the combine, as they did not cut prices. The new company has a capital of \$5,000,000. The output of salmon will be limited to 500,000 cans a year.

THE officials of the Southern Pacific Co. are taking steps to convert from a narrow to a broad gauge the line known as the Santa Cruz division, which runs from this city to Santa Cruz. All freight shipped from stations on the road to points on broad-gauge roads, or out of the State, has to be transferred from the small cars to the large ones, and the business has grown so great that the rehandling has proved a nuisance. The officials deny that any change will take place for many years to come, but the fact remains that many preparations are now being made to lay a third rail in order that broad-gauge freight trains may be run over the road. Work of laying a third rail from Alameda to Los Gatos, at the foot of the Santa Cruz mountains, is being carried on and the officials expect to have broad-gauge trains running between these points by next fall, that they may take out the large fruit crop without rehandling it. None of the many tunnels on the road are wide enough to admit of the passage of broad-gauge cars, and experiment is about to be made to ascertain the cost of enlarging the narrow-gauge tunnels. Lumber and timbers are now on the ground at Rincon, a point two and a half miles north of Santa Cruz, where there is a short tunnel and which was chosen as the best place to learn the cost of remodeling tunnels.

Personal.

MR. FELIX CHAPPELET went up to the Mayflower mine, Placer county, this week.

A. LEONARD, mining engineer, has gone to Chicago on very important mining business.

PROFESSOR SCHABERLE of the Lick Observatory left for Chile this week, where he will observe the eclipse of the sun in April. He will bring back a number of photographs.

THE Board of Regents of the State University of California have adopted a resolution detailing Professor Barnard of the Lick Observatory to make a tour of inspection among the leading observatories of Europe in the interests of astronomical science, and granting him six months' leave of absence, with pay, for that purpose.

ISRAEL LAWTON of Oakland has been appointed a member of a commission composed of representatives of several States to examine and test the weight and fineness of coins reserved at the several mints of the country during the last calendar year. Judge Lawton was formerly superintendent of the U. S. Branch Mint in this city.

GARDNER F. WILLIAMS, formerly of Oakland, is now general manager of the De Beers Consolidated Diamond Mines, at Kimberley, South Africa. He visited California last summer, and on his return to his post of duty was given a fine reception. The Diamond Fields Advertiser, in speaking of the occasion, says: "All the officers and many of the employees of these richest diamond mines in the world attended, and around the hall were hung such mottoes as 'Welcome to Kenilworth,' 'The Workingman's Friend' and 'Respect Cannot Be Bought.' After Mr. Williams had been welcomed by the chairman of the company, who paid a great tribute to his ability, the honored guest was handed an address beautifully illuminated and surrounded by a picture of Mr. Williams in a diamond on behalf of the employees. The recipient responded in a speech expressive of good-will toward his workmen." Mr. Williams is well-known in this State, where he resided for many years, and where he got his first practical mining experience. He was an especially skilled hydraulic miner, but quit that work when the debris troubles began.

Miners and Experts.

SAN FRANCISCO, Jan. 23, 1893.

TO THE EDITOR:—A short time ago an article appeared in the MINING AND SCIENTIFIC PRESS, signed "Mining Sharp," which proves very little, as it evidently exhibits personal bias. The party is no doubt right in what he says of the majority of miners; they are, as a rule, a cranky, unreasonable set, and have a remarkable facility for standing in their own light. Still, we could not do without them very well, as they are the pioneers in opening up mines and preparing properties for those who come after them. But with all the reason I for one have to complain of the class, give me the miner every time before the so-called expert that "Mining Sharp" seems to think so highly of. I will not deny an educated expert ought to be something of some use, but it is very hard to say for what. What expert ever found a mine? What expert has ever owned one? Men graduate from law and medical colleges, military academies and technical schools and become great lawyers, doctors, generals and mechanics, but who ever heard of a graduate from a mining school owning a great mine or becoming a millionaire from mining? I know well that Haggin, Tevis, Hayward, Hobart, Daly, Grayson and a host of others never got their millions out of any such institution. For one thing, they simply let the ordinary miner grub away till his prospect is opened sufficiently, when they purchase and develop it, and when it is ready for machinery call in the foundryman and set to work grinding out dividends—all without having an expert within a thousand miles of them. There might be one case in a million, but there is not a mine in this State, if on the coast, that owes its first origin, development and final triumph solely and individually to the man with a diploma. There was a time when California mines were salable in London, but the business is dead as a stone at present, and will never revive. I happen to know something of the deals that gave us our quietus. Since 1886 we have sold in

London the Valley Gold and the Victors in San Bernardino, the Union at San Andreas, the Glen in Calaveras, the Amador near Jackson and the Josephine, in Fresno, of fragrant memory. All these mines were "expert productions" of the first order, being passed on by local or foreign customers of that ilk. The Josephine "Mining Sharp" ought to roll about in a very ocean of sweetness. Here the mine was bonded by Expert No. 1 (one of the shining lights of the order) and sold to Expert No. 2 in London, who was the head of an expert organization there. No. 2 employed No. 3 and No. 4 of the local board to pass upon the mine, which was done favorably, and the mine floated with such eclat and success in London that a broker writing to me about that time said he had an order to get 100 shares, and such was the furor for the stock that he could only deliver 20. The mine was put up at 60,000 pounds, and went to 120,000, at which no doubt most of the shares were disposed of; but in a few months it turned out to be one of the most shameless fiascos ever put on the market.

I mention this case particularly because there was so much of that "expertism" about it, which mining sharps seem to admire so, and because it exhibits more clearly than any other what experts really amount to, as I do not believe there was a particle of dishonesty in this whole transaction, but incompetence, and nothing but incompetence from first to finish. I remember a party had a mine for sale at the time with a shaft almost 400 feet deep, maybe more, and two 400-foot drifts at the bottom in ore, which at one end was over 20 feet wide and showed no walls. This was taken to the principal Josephine expert, and, being a property of extraordinary merit, was of course sent a packing out of the door with the speed of lightning. This mine was soon afterward purchased by one of California's leading millionaires, and has now among other articles of equipment a ten-stamp mill from that very same Josephine mine, purchased when the machinery of the latter was scattered to the four winds by the auctioneer or sheriff. Could the irony of fate go further?

There are some roving mine promoters in the West, who have sold a couple of silver mines in the last two years, and as the sales have been successes, much credit ought to be given to the expert they employed. What does all this amount to? These promoters look very big, wise and important, hawk around till they come across some mine that not only has merit, but has a loog record, and is producing at the time being. What has the expert to do in this case but to report actual facts? As the facts are all in favor of the mine, how can he make a mistake? Here is a mine with a shaft 600 feet deep; four levels have been run in ore on each side of the shaft an average distance of say 500 feet; the vein is 30 feet wide, going 30 to 40 ounces in silver. Level No. 1 has been worked out and there are the books to show that for three or nine years the gross yield, expenses and profits have been so much. The expert appears on the field, fills himself to bursting from the foreman, under-foreman, miners and everybody else about the place from whom he can pick up a few crumbs, down to the logger and Chinaman. Then he gives it all off as his own, and, to still further enhance the importance of the production, it is padded out with a great many pages and columns of figures, copied from the company's books, as to the gross receipts and dividends referred to. The promoter who has a reputation as an expert himself, with a reckless daring that cannot be too highly reprehended, writes a little ten-lie "Me Too" report, which is appended to the main document and the whole is ready for general consumption. The mine being a good one is sold; it goes on doing, of course, what it always had been doing before the promoter had ever heard of it. The thermometer of enthusiasm keeps rising with every dividend till you have half of London ready to put up their last copper on the judgment of the promoter and his unapproachable assistant. I mention this case to show what this experting amounts to even in its most favorable aspect, where it is a so-called "success"; but even here I will wager if the mine had a shaft 1000 feet deep, if it had ten drifts therefrom, 1000 feet long; if the vein was 50 feet wide and went 100 ounces to the ton, it is all right; but if there was no mill on it, no past record, no present production, and the promoter and his expert were left all alone with it and the "rocks," as Mining Sharp puts it, I bet they would not know where they were. Verily, in mining matters, "Great is King Humbug," and the Lord Chancellor of this court is the "Mining Expert."

AMADOR.

The Best Deposits of Tin.

The mineral resources of the Indian or Malay Archipelago are known to be very great, but up to the present systematic mining operations have been confined to the wonderfully rich and pure stanniferous deposits of the islands of Banca and Billiton. The tin obtained from the ores found in this part of the globe is the most unsophisticated produced. A recent analysis of Banca metal gave the following results:—Tin, 99.961 per cent; iron, 0.019; lead, 0.014; copper, 0.006. According to the latest statistics available, there are in the island of Banca some 200 mines worked by private companies, while about one-half that number is exploited by the Dutch Government. The island itself is divided into nine mining districts. The miners are members of the Kongsis or Chinese trade-unions, which effect the labor contracts with the Government. The cost of production in the last fiscal period amounted to 26.14 Dutch florins per picul, a weight of approximately 135 pounds. The sale price attained an average price of 84.82 Dutch florins, so that by a total output of 65,964 piculs a net profit of 2,805,000 gulden, or £233,750, accrued to the government of the Netherlands. The mines on the island of Billiton are in the possession of a private concern. This organization pays a royalty to the Government of 3 per cent of the gross annual yield. In the preceding financial year the authorities received under this agreement 2,376 piculs, out of a total of 76,183 piculs, a quantity which realized on sale about £17,000. The mining board which controls the Government works is an offshoot of the Dutch ministry of commerce, and it consists of 15 engineers and 24 overseers.

School-Bred Miners and Practical Men.

REDDING, SHASTA CO., Jan. 21, 1893.

TO THE EDITOR:—At variable periods the PRESS is regaled with an article written by some sorrowful soul, who is generally one who speaks from his own sad experience, and if we follow his course back a little ways, our sympathy may be aroused and we may feel like saying: "He's a good fellow; pity he can't make things stick." Such a one sends up the usual wail, over the non de plume of "Mining Sharp," in your issue of Jan. 7th. Such articles are never written by the progressive, successful man. "Sharp" feels hurt at the wrong-headedness of mineowners who persist in calling in the services of practical men instead of the "professionally, scientifically educated engineer." No doubt the business world, keen and generally unerring in its instinct, has learned to shun the school-bred miner. It has seen the wrecks of fortunes, ventured upon the well-paid reports of the highest professional authorities, scattered all over the land. From the days of the Fremont estate in the early fifties to the Bears' Nest fiasco in 1890, the track of the professionally, scientifically educated mining engineer has been one of ruin.

It may be questioned how far the term science is applicable to knowledge of mining. I feel pretty certain that there is no science of mines. No one has yet demonstrated how metalliferous veins are formed, nor the source of the mineral aggregates which form the veins, nor the method of their deposition. There are plenty of geological hypotheses but no geological science extending so far. There is no known law controlling the form or extent of metalliferous deposits, either horizontally or in depth, or limiting the bounds either of age or of rock within which they may be found. So long as we are ignorant of the law, we cannot formulate a science. Therefore, the term scientifically educated is so far a misnomer.

In the field of the unknown all are equal. It is true that many of the methods of procedure used in mining art are scientific operations. Thus, if we want a set of plans of a mine, we call in a surveyor who does the work accurately by processes which are thoroughly scientific, even though he may have no idea of what part of the work is mine or what is common country, or never had seen a mine before.

If we want to know the composition of any material encountered, we give a sample to the chemist, and he determines its chemical composition without any regard to whether it came from a mine or not.

The metallurgist takes the product of the mine and reduces the metals from the ores, even if he has never seen a mine in his life.

These scientific operations are accessories of the art, but they are not necessarily any part of it. In other words, they can exist in places where there are no mines and be operated by men who have no knowledge of mines, or a man may have the highest education possible to be attained in all three of those pursuits and still be utterly ignorant of what constitutes a mine.

How can the art of the mining expert be taught? There is no royal road to it except through the hard ways of experience; only by active, intelligent work and observation in the mines can the secrets be wrung from the unyielding rocks; only by close contact with nature as she unfolds her story, which awakens within us the perceptive faculties and by long-continued use disciplines the judgment, can we place a correct interpretation upon indications which often, more than the developments actually made, pronounce the value and extent of the mine.

The mining expert is he who, by long experience in the mines, under all the various conditions of time and place, has preserved the partnership of an intelligent brain with indefatigable industry of hand; who, with an innate love for his art, has had his perceptive faculties awakened so that he is able to trace the lines drawn by nature's hand, and interpret them aright. Fortunate is he if also he can interpret his thoughts with clearness and grace, and paint in words of vivid truthfulness the story of the rocks. Too often, indeed, the practical man is unable to express himself in the language which will convey the truth in the most pleasing manner, and here he is at a disadvantage with the school man. But he has sweet revenge. Of late years the majority of the men sent to examine mines for the big mining firms are men who do not refer to college experiences to any great extent in their conversations. It is a case of the survival of the fittest. J. H. MORTON.

Obstacles to the Sale of Mines.

SAN FRANCISCO, Jan. 23, 1893.

TO THE EDITOR:—In a former communication I expressed my views very freely on the subject of exaggerations in mining reports. I think something might be said of the mystery preserved by mineowners as to the past and present product of a mine for sale. There seems to be a disposition to hide all facts relative to this important information from the purchaser. It is simply folly to attempt to hide the real condition of the mine from the expert who will be sent to examine it, when the facts must come out, of the productiveness of the mine, inasmuch as assays of the rock determine its value, and the cost of mining and milling is easily determined when all the merits and demerits of the mine can be arrived at.

Many mines are run in a very slipshod manner, no record of product and expenses being correctly kept, and when the owner offers his mine for sale, the first question asked is, "What are you producing?" The absence of any record at once casts a suspicion on the merits of the property, while a record and correct account of product and expenses would be calculated to inspire confidence to say nothing of its being more business-like.

Another obstacle in the way of the sale of a mine, is the refusal of owners to give the necessary time to the middle-man to find a customer for it. The broker can hardly af-

ford to give his time and efforts in seeking the capital to accomplish the sale, on the uncertainty of being able to obtain the property when he has found the customer, as in case of any improvement in the mine the price may be advanced; again, parties contemplating the purchase, will not spend their time in an investigation or go to the expense of sending an expert to inspect a mine on any such uncertainty. The broker must exhibit his evidence of authority to sell before he can obtain the attention of capitalists.

It is a peculiarity and characteristic of the mineowner who has waited for a purchaser for years, when finally, there seems to be a possibility of a sale, he at once imposes conditions and restricts the time for the transaction in such a period as to defeat the chance of a sale. He demands immediate action and limits the time for the first cash payment to a date so near at hand that the parties decline to undertake the investigation; or he wants a deposit on a bond, if given. Such conditions have lost the sale of many mines, when the policy would be to give the utmost period of time he can, unless, indeed, he has a prospect of sale from another source.

It may be urged that it is unwise to tie up the property for months without some compensation and the argument is used that a bond without a penalty involves no responsibility on the part of the broker. He may sell or he may not; but it should be borne in mind that the broker loses his time and labor in the effort in case of failure to sell, with no compensation therefor; at any rate the mineowner must make concessions if he wants to sell his property, and he may decline to give a bond if he has little or no faith in the broker; that is his privilege. To give a bond on a mine has its objections, it is true, but it seems to be an almost imperative necessity and one of the chances that the mineowner must take if he is desirous of selling. If not, then he can be more independent, but his opportunities for a sale will doubtless be greatly lessened. MINING SHARP.

Cyanide Notes.

"Cyanide is King" is to be the legend inscribed on the base of the monument erected in the Kimberley (South Africa) Exhibition Hall, to convey some idea of the magnitude of the Witwatersrand output, and the title would appear to be well-merited. In a recent report of the African Gold Recovery Company, who use the MacArthur-Forrest process, it was shown that the gold recovered by the process, in proportion to the total output of the Rand, has increased from 7½ per cent. in November, 1891, to 12 per cent. in March, 1892, and 15 per cent. in June. The August return gives 16,392 ozs. out of a total of 102,322 ozs., being equal to 16 per cent., and the September return is still larger. Many of the companies are retaining their tailings until they are able to erect their own cyanide works, and even granted that not another stamp is erected for the next six months, within the period there will be an appreciable augmentation in the yields.

The gold output of the Witwatersrand mines for September reached the magnificent total of 107,851 ozs., or 5,529 ozs. in advance of the yield for the previous month and 4,501 ozs. over June, when the previous record of 103,350 ozs. was established. The yield for September, 1891, was 65,601 ozs., and the figures have since gone up and up as follows: October, 72,793 ozs.; November, 73,393 ozs.; December, 80,312 ozs.; January, 84,560 ozs.; February, 86,649 ozs.; March, 93,244 ozs.; April, 95,562 ozs.; May, 99,436 ozs.; June, 102,350 ozs.; July, 101,279 ozs.; August, 102,322 ozs.; September, 107,851 ozs. In September the Robinson produced 11,400 ozs. from its own ground, and 1,911¼ ozs. from bought concentrates. The Langlaate Estate yield was 9,308 ozs.; the Crown Reef, 6,384 ozs., and the New Primrose, 6,055 ozs. Five companies have exceeded 3,000 ozs., viz., Geldenhuis Estate, 5,223 ozs.; Ferreira, 3,936½ ozs.; Nigel, 3,870 ozs.; Simmer and Jack, 3,409 ozs., and City and Suburban, 3,210 ozs. Twenty-three companies produce between one and 3,000 ozs. In the nine completed months of the present year the yield has reached the fine total of 873,245 ozs., giving a value, in round figures, taking £3 10s. as the average price, of £3,060,000. In all probability, it is stated, the output from the Rand for the next year will reach a value of £5,000,000, or about \$25,000,000.

A dispatch from Ward, Colo., dated January 5th says: The Cyanide mill of the Puzzler company is working smoothly and giving great satisfaction. About 15 tons of ore is being milled each day, and Supt. S. C. Houck claims to be saving from 92 to 98 per cent. of the actual value of the ore. The capacity of the mill will soon be increased. The MacArthur-Forrest process is finding great favor in Boulder county, and now mills are being talked of by the score. The great Ballarat mine, located in Ballarat Gulch, will erect a one-hundred ton mill on their property in the immediate future. This process will revolutionize mining in Boulder county during the present year.

The Forfeited Railroad Grant.

The railroad lands belonging to the Southern Pacific Company in the southern part of the State, which were declared forfeited to the National Government by a recent decision of the United States Supreme Court, have been officially described or designated as follows:

The grant includes all unoccupied Government land lying 30 miles on each side of the railroad track from the ocean shore at San Buenaventura to Los Angeles. It then continues along for 30 miles each side of the surveys from Los Angeles through the county of San Bernardino to the Colorado river at The Needles. A Los Angeles expert, who had made a specialty of investigating these lands, states that "there are none fairer in the southern part of the State." These lands embraced within the grant, which are designated as being "desert waste," are susceptible of the highest cultivation. The Wright irrigation district, which lies contiguous to part of the forfeited grant, fur-

nishes an illustration of the productive capacity of these lands. In Ventura county all the available valley lands have been sold. In the mountainous districts, however, there are thousands of acres worth taking up. In Los Angeles county, in the northwestern part, there are but few acres of any value remaining, and the same state of things exists until within a few miles of the bounds of San Bernardino county is reached. From there to the Needles plenty of vacant tracts can be had for the taking up.

Scrap Iron and Copper.

When the Anaconda and St. Lawrence mines were opened up in Butte it was found that the water contained in the fissures was strongly impregnated with copper in solution—so much so that iron cages, cars and tools of all kinds were quickly destroyed by the affinity of the copper for the iron. And that is the case to-day. Only a few weeks' immersion in the waters reduces a mass of iron to pulp, and this requires that all material used in the mine composed of iron and steel be replaced at frequent intervals. After three or four weeks' constant use in the mines, a cage or car is found to be pitted like the inner bark of a tree after an attack by insects. The water of the St. Lawrence mine is pumped out and flows across East Broadway down into the valley. For a long time this water went to waste, as no method was known of extracting the copper from it. After awhile, however, a discovery was made that is being utilized to good advantage.

Some tin cans found their way into the small stream, perhaps through the medium of boys at play. In a short time it was noticed that the cans had every appearance of being made of pure copper, so thickly were they coated with that metal. These were regarded as curiosities by all who saw them, but presently they attracted the attention of a man who saw a little further than most people. His name was Miller, and he began to experiment and found that old cans and iron junk thrown into the water were soon destroyed, and in their stead was a rich deposit of copper. He had an idea that it would pay to extract the copper from the water by this process, and immediately purchased the exclusive right to the water for a small sum of money.

Then he put in a series of reservoirs and tanks along the little gully where the water ran. These he filled with all the old refuse metal to be had in the town, including barrel hoops. In the course of about six months he made a clean-up and found that the old junk was totally destroyed, but in its place was a sedimentary deposit in the bottom of the reservoir and tanks assaying 80 per cent copper. He then enlarged his plant somewhat, and is now deriving a handsome revenue from this peculiar mine. His annual income is estimated at from \$10,000 to \$15,000. All the labor necessary is in cleaning up and charging the batteries of the reservoirs.—Butte Inter-Mountain.

A New Refining Process.

In these days of low prices for silver bullion and other products of silver mines, it behooves the owners to look out for cheaper methods of reduction and for appliances that will reduce the cost of preparing their product for market. The Ontario Company is alive to all such features, and recognizing the slowness and the cost per ounce of refining Marsac sulphides by the Stedefeldt process, has decided to make a complete change and substitute a new method recently patented by Mr. F. P. Dewey, and arrangements are now being made for all alterations necessary in changing from one process to the other. Mr. Dewey is in the city and was interviewed by a representative of the *Record*, who obtained the following information concerning the new process: The patent is owned by the Dewey-Walter Refining Co., all the members of which reside in Washington, D. C. The letters patent have not as yet been issued owing to one or two slight conflicts in the Patent Office, but no trouble is anticipated as to final results. The process is much shorter and cheaper than any other now in use, and the metal requires less handling. Silver is refined to 9.98 and gold to 9.90, both of which are fully up to the requirements of the Government mints, hence the product will not have to be re-handled by the Government or other purchasers. The process makes a complete separation of the gold, silver and copper, the latter appearing in the form of bluestone, an article used in the Russell leaching process. The method employed is known as a wet process, and does away with the matting and roasting furnaces of the Stedefeldt plan. Mr. Dewey has taken a contract to reduce all the Marsac sulphides to bullion at the uniform rate of 1½ cents per ounce of bullion produced, and will commence on this year's product of sulphides. The Stedefeldt process will be operated until the product for 1892 has been reduced to bullion, when the present appliances will be torn out and the Dewey appliances placed. The building will not be enlarged unless it is decided to put in a new melting plant, and that may be done to save cost of hauling bullion to and from the Ontario mill, where the melting is now done. It is expected that the tearing out of the old and the placing of the new appliances will commence in about two weeks. Mr. Dewey will remain in the city until the new plant is in thorough working order. Should the plant prove successful, and Mr. Dewey knows it will, it will be placed in the new Ontario mill when that is completed.—Park (Utah) Record.

PROFITS OF COPPER-MINING.—The Calumet and Hecla, the great copper mine, has declared \$2,000,000 in dividends for the present year, this making a total dividend paid to date of \$38,850,000. Assessments have been levied to the amount of \$1,200,000, and the capital stock is \$2,500,000. To those who have held the stock from the time the mine first began to yield a profit, the gain has been enormous, but there are comparatively few shares so held. Much of the stock has been purchased at a high figure, and upon its present selling price it pays only about 7 per cent.

There have been some difficulties in placing the bonds of many of these districts.

The securities provided are new, and capital is always conservative and fearful of new schemes. The need of a canal and irrigation works in any district indicates *prima facie* the aridity of that district, with a consequent lack of population in its vicinity. Capitalists want the most ample immediate security for their loans, and are not willing to invest on prospective improvements and a consequent advance in value. This is especially true of eastern capitalists who have not yet overcome their early prejudice against the great American desert.

The advantages offered by the Wright law, however, are amply illustrated by the fact that, in some cases, communities with ample and well-secured water rights, owning paying, and improved farms and orchards, have organized under its provisions in order that they may avail themselves of its benefits in working as a unit instead of as individuals.

ADVANTAGES OF IRRIGATION.

The effect of water upon land may be classed under two general heads—chemical and physical.

The chemical effects may again be divided into:

1. Supplying fertilizing qualities, contained in the water, to the soil.
2. Changing the chemical composition of the plant food already existing in the soil.
3. Dissolving and preparing the plant food of the soil and fitting it for absorption and assimilation.
4. The deposition of beneficial or injurious salts.

The physical effects are fewer but no less important, and are—

1. The softening of hard soils and rendering them suitable for working.
2. The disintegrating of the harder particles and making the texture of the soil finer.

The matter of fertilization is one of the gravest importance to the Eastern farmer. The continual cropping of the soil has so deprived it of the constituent elements of plant life as to have rendered, in some cases, land worthless that was valuable until such continual cropping without making any returns had rendered the soil barren; in other cases, the farmer has to return a very large percentage of his earnings to the soil in the way of artificial fertilizers, in order to supply the necessary plant elements. While it is unquestionably true that we in California shall have to supply some portion of these elements, the water from our mountains, and even from our artesian wells, is so freighted with the larger part of them as to reduce the cost of this requirement to a minimum.

These constituent elements, which are drawn from the soil and absorbed from the air, are potash, soda, lime, magnesia, brown oxide of magnesia, iron oxide, alumina, phosphoric acid, sulphuric acid, silica, chlorine. These are usually found in abundance in all virgin soils, but continual cropping without returns in some form will ultimately exhaust them, and as a result, crops are light and unprofitable.

Our irrigating water is generally derived from the mountains. It falls in winter as rain and snow, follows the surface of the land to the main channels, and gathers up on its way all these elements, or it penetrates the soil, washes down the rocks, and breaks forth in the spring, and finds its way to the main stream. In either case the necessary elements of plant life are gathered up, held in solution and are ready for deposition on the soil to which the water finally finds its way. In the gathering of these fertilizers the water is aided by the heavy frosts of the mountain regions, which work continually, disintegrating the rocks and pulverizing the rich mountain soil, releasing all the elements required by plant life, which the water in its turn gathers up and carries on their life-giving mission.

The duty of water in irrigation is to supply the sap, and to carry with it the necessary food which the soil contains or which the water brings in solution, and thus forms the plant and the fruit. This it does by dissolving the plant food of the soil in which the plant is growing, changing its chemical composition and forming it anew in such shape that the plant can absorb and assimilate it. Coming charged, as they do, with so large a part of these necessary qualities, and finding others in the soil itself, our irrigating waters are supplied with perfect conditions, and, in that wonderful laboratory—the tree or plant—converts these elements into fruits or grain or flowers, as desired. And it is largely to these qualities of our water and soil that California owes its advantages as a fruit-producer.

Besides the great saving in the outlay for fertilizers, and the greater productive power of his land, the farmer or fruitgrower in the irrigated region has other great advantages over his brother in the rain belt.

He has no fear from the effects of drought.

He has learned to overcome all danger from this source. Here every year is a drought year, but with irrigation the effects of drought are rendered nugatory and every year is made a year of full and abundant crops.

OUR ARID LANDS.

Irrigation has within a very few years assumed a position of importance that few would have dreamed of 30 years ago. The first efforts made in this direction were by the Mormons who, arriving in Salt Lake valley in 1847, found a large basin of most fertile soil producing nothing but sagebrush, while the mountains rushed perennial streams on their way to the lake. Irrigation was a matter of necessity with them, and locating on these streams they diverted the water to the land and the results were surprising. The yield of wheat and corn and vegetables was enormous. While the system of irrigation introduced by the Mormons was crude, it served to show what arid lands would do when under water, and the great boast of this people was that they had "made the desert blossom as the rose."

The steady increase of population in the East, the absorption of all available Government lands within the limits of the rain belt, had a tendency to push population into the arid district, and gradually irrigation has obtained a foothold until it has grown to proportions that are surprising, and now, instead of speaking of the great American desert, we allude to the great West as the irrigation empire. This empire includes all of Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, North and South Dakota, Utah and Wyoming, and large sections of Kansas, Nebraska, Oregon and Texas, with over 7,000,000 people dependent upon it for homes and food. The importance of this subject first made itself appreciated in Congress as late as 1874-5 when the first inquiry into it was ordered made, and an examination of the San Joaquin valley, with a view to its reclamation by irrigation, was made by Government agents. Ten years elapsed before it received further recognition, at which time attention was again called to it by the arrival of an Australian Royal Commission to investigate our irrigable area and methods, when the Department of Agriculture detailed Richard J. Hinton to prepare a report on "Irrigation in the United States." Three years after this Congress provided for an irrigation survey under direction of the United States Geological Survey, and their inquiry into the condition of the arid lands was ordered by the Senate, having in view their possible reclamation by irrigation.

The rapid growth of irrigation is shown by the fact that when the first report was completed in 1886, the area of land reported as reclaimed by irrigation was 5,500,000 acres, a large proportion of which was used for pasture and the growth of natural grasses. In 1891 the total area under ditch is given at 17,086,034 acres.

The following table for 1891, given in the report of the Office of Irrigation Inquiry at Washington, will show how this area is distributed:

States and Territories.	Estimated Under Ditch.	Area Under Cultivation 1891.
Arizona.....	880,000	315,000
California.....	4,600,000	3,650,000
Colorado.....	3,007,050	1,800,000
Idaho.....	1,300,000	330,000
Kansas (west of 97 long.).....	900,000	120,000
Montana.....	1,250,000	410,000
Nebraska.....	200,000	40,000
Nevada.....	150,000	75,000
New Mexico.....	700,000	465,000
North Dakota.....	2,500	2,000
Oregon.....	125,000	45,000
South Dakota.....	100,000	54,000
Texas.....	1,500,000	160,000
Utah.....	735,000	423,000
Washington.....	175,000	75,000
Wyoming.....	3,031,484	185,000
Totals.....	17,086,034	8,049,000

From this table it will be seen that California leads in the quantity of land under irrigation systems and in the amount of that land now under cultivation.

Taking the area still open to settlement in the arid regions, as soon as the water which is now going to waste is properly preserved and we have an empire capable of supporting an enormous population. The States which come within this irrigating area are:

	Acres.	Sq. Miles.
California.....	100,992,640	157,501
Oregon.....	60,975,360	95,274
Utah.....	54,380,800	84,970
Washington.....	44,769,160	69,994
New Mexico.....	77,683,640	121,201
Nevada.....	71,737,600	112,090
Arizona.....	72,906,240	150,932
Colorado.....	66,830,000	104,600
Wyoming.....	62,646,120	97,883
Idaho.....	55,228,160	85,294
Montana.....	92,016,640	143,776

To this add 100,000 square miles, or 64,000,000 of northern and western Texas, and

the whole of Kansas and Nebraska west of 97 long., and some idea of the area and importance of our irrigation empire can be formed, and it serves also to show the importance and necessity of governmental aid in its reclamation. Within the arid region there is now a population of 7,000,000 souls. This number is rapidly increasing, and from estimates made by the office of Irrigation Inquiry, \$64,000,000 have been expended in irrigating works, as follows:

Under ditch the acreage given represents (at service of 250 acres per mile) a total ditch length of.....	Miles.
Total of actual expenditures (not of capitalization) for the mileage given at an estimate of \$3 per acre will be.....	Cost.
Allowing actual expenditures for other works, not under ditch mileage, and its necessary appurtenances, we may estimate the total at about.....	\$55,699,321
	\$64,000,000

These figures are certainly conservative, and the actual expenditures for irrigating works will probably far exceed them. Enough, however, is shown in the way of population, capital invested, and area to be reclaimed, to show the necessity for extensive Government aid in this important work.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISSELL, 650 Market street, Chronicle Building, San Francisco.

Professional.

A. LEOPRED, Mining Engineer.

Graduate of Laval & McGill.

Head Office, QUEBEC. Branch Office, SHERBROOKE. Branch office, MONTREAL, 17, Place d'Armes Hill.

STEPHEN H. EMMENS,
Consulting Engineer and Chemist,
Youngwood, westernland County, Pa.
SPECIALTIES: Nickel, Tin, Dry Placer Development, Treatment of Refractory Ores, Electric Heating and Smelting.

**School of Practical, Civil, Mechanical,
Electrical and Mining Engineering.**
Surveying, Architecture, Drawing and Assaying,
728 MARKET ST., SAN FRANCISCO, CAL.
Open all year.
A. VAN DER NAALDEN, President.
Assaying of Ores, \$25; Bullion and Chlorination Assay, \$25; Blowpipe Assay, \$10. Full Course of Assaying, \$300.
ESTABLISHED 1864. Send for Circular.

C. A. OGDEN. W. N. JENY.
JEHU & OGDEN,
Chemical Laboratory and Assay Office.
628 MONTGOMERY ST., San Francisco.
ROOMS 46 and 47 MONTGOMERY BLOCK.
Ore Assays, Analyses of Minerals, Waters, all Technical products, etc., made.

EVERETTE'S MINING OFFICE.

(Pioneer Mining Geologist's Office of the Pacific Northwest.)

Mining Law, Mine Examinations, Metallurgy.

ASSAYING AND ANALYSIS.

"Consulting Associate Mining Attorney at Law."

Will examine and report upon "Title and Exact Value" of GOLD, SILVER, LEAD, COPPER, COAL, IRON, CLAY or other MINERAL PROPERTIES to any part of the world. Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.

DR. WILLIS E. EVERETTE, 1318 E. ST., Tacoma, State of Washington, U. S. A.

Nevada Metallurgical Works.

NO. 28 STEVENSON STREET,
Near First and Market Streets, S. F.

O. A. LUCKHARDT, Manager. ESTABLISHED 1869

Ores worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, etc.
Working Tests (practical) Made.
Plans and Specifications furnished for the most suitable Process for Working Ores.
Special attention paid to Examinations of Mines; Plans and Reports furnished.
C. A. LUCKHARDT & CO.,
(Formerly Hubbs & Luckhardt,
Mining Engineers and Metallurgists.

WELL MACH'Y All Kinds, Water, Gas, Oil, Mining, Ditching, Pumping, Wind and Steam; Heating Boilers, etc. Will pay you to send 25c. for Encyclopedia of 1500 Engravings. The American Well Works, Aurora, Ill., also, Chicago, Ill.; Dallas, Tex.; Sydney, N. S. W.

Metallurgy and Ores.

SELBY SMELTING and LEAD CO.,

416 Montgomery St., San Francisco

GOLD AND SILVER REFINERY And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF—
**BLUESTONE,
LEAD PIPE,
SHEET LEAD,
SHOT, Etc., Etc.**
ALSO MANUFACTURERS OF
Standard Shot-Gun Cartridges,
Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scaffolds, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at the lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful MacArthur-Forrest Process. Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. Tabor, Pres.; LEONARD GOW, V. Pres.; H. A. JONES, 2d V. Pres.; P. GEO. GOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Sec'y; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
The Cassel Gold Extraction Co., Glasgow, Scotland, New Zealand, South Africa, New Z.aland, & elsewhere, Eng.

General Office of Company:
Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingstone Gold Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champie's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned King and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Co., Gold Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the Mac Arthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process. If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ores to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubs especially constructed according to our diagrams, for triturating, setting and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton. The most desirable class of ores for this process is the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,

P. O. Box 926. Gen. Mgr. and Secretary.

Mechanical Progress.

Transmitting Strength of Shafting.

It is generally pretty well known, says the *Scientific Machinist*, that a shaft will transmit power in proportion to its running velocity and therefore the faster a shaft runs the lighter it should be within reasonable limit. The use of extremely heavy shafting is not advisable under any circumstances, unless actually needed to perform the work required. Some imagine, says the *Mechanical News*, that a large shaft affording a very strong margin of safety, is the most economical to use; that, however, cannot be considered a logical and tenable mechanical position, unless tempered with sound judgment and much wisdom, sufficient of both to select properly. That there should be an ample margin of strength no one will attempt to deny, but shafting multiplies in strength so rapidly as sizes increase, that the unlightened are apt to make the selections much too large when aiming at only ample strength margin. To show how easily uninformed mechanics may make mistakes of that kind, it is only necessary to say that a three-inch shaft has nearly three and a half times the transmitting strength of a two-inch shaft. None unaware of the fact would ever guess at that difference and may fall into the error of selecting a three-inch shaft to safely do the work of a two-inch. To more favorably illustrate the difference, it can be stated that a two-inch shaft, properly sustained with bearings at reasonable intervals, will safely transmit 20 horsepower at 100 revolutions per minute and at the same time resist the transverse strain due to weight of pulleys and the pull of belts necessary for transmitting that much power. Under like circumstances and equally proportionate conditions, a three-inch shaft will just as safely transmit 68 horsepower at 100 revolutions per minute. Shafting should never be so large as to make it absolutely rigid; on the contrary, it should be to a fair degree elastic, with an ability to give and take between the power and the work. When too rigid, unless away above all requirements in size and strength, the liability to break is increased, especially if the work is of an abrupt and severe character. Long lines of shafting having the power at one end and the work at the other, should be graduated in size; the work end being of a size required to safely do the work and the power end larger, in proportion to the length of the shaft or the distance between power and work. If such shafts be of the same size the entire length, and that a fair working size only, there will be too much elasticity in the aggregate, which will tend to gradually weaken, distort, and, in the end, destroy the usefulness of the shaft.

Electric Heating.

Exploiters of electric heating apparatus are now beginning to have experiences similar to those undergone by the electric light pioneer. In the early days the canvasser for central stations had to combat the gas man and sell his product at a higher price. It seemed to many in those days that it would be an impossibility to make any serious inroads in the territory occupied by an illuminant so comparatively cheap and long tried as gas. But when one takes a retrospective view of the progress made and studies the difficulties that were overcome, the secret of electricity's success becomes evident. In a word, no one would now venture to assert that the incandescent lamp was not in every way superior to gas; and it is, too, in one sense a more expensive illuminant. Electric light is now the best artificial light obtainable, and it is for this reason that so many demand it in preference to gas. It is this superiority, therefore, of the electric lamp over its rival, gas, that secured its general adoption.

As it was with the incandescent lamp, so, apparently, it will be with the electric heater. The same ground, doubtless, will have to be gone over. The cries of "uneconomical," "too expensive," "a luxury," etc., are already beginning to be heard. But this time the electric heating pioneer has a good precedent to employ in his arguments—in fact he has two precedents, for applications of the electric motor furnish also most excellent illustrations of the benefits to be derived through the employment of an apparatus that does not make necessary the consumption of fuel at the point of service. Almost every day marks a new application of the electric heater under circumstances where, say, steam heat is not easily obtainable or the ordinary stove desirable. For instance, the electric heater has found its way into the conservatory, and the latest and most novel suggestion is that through the use of a

special form of heater, electricity be employed in the hospital to heat the poultice and warm the sick man's bed.

There is no doubt that the electric heater has come to stay. For a time, though, it will be employed in special lines of service. But its field of usefulness will unquestionably be a rapidly broadening one.

Welding Nickel and Steel.

At the October meeting of the Engineers' Society of Western Pennsylvania, Mr. Joseph H. Eastwick read a paper on the "World's Supply of Nickel." He mentioned the nickel deposits at various places in the United States which may be valuable, principally in Oregon, Nevada and North Carolina. A trial of the North Carolina ore by Mr. Mixer, of the Edgar Thompson Steel Works, was rather discouraging. It averaged about two per cent of nickel, although samples have been obtained running up to ten per cent. The Nevada ores are abundant in quantity and comparatively rich, but they are arsenious of nickel and difficult to refine. They are also far from railroad facilities. The Oregon ores are of the silicate class and have not been developed in commercial quantities.

During the discussion the question of welding nickel and iron was brought up. Mr. Mixer said that he had examined rolled sheets made in Cleveland, O., of nickel and steel. Looking at the edges of the sheet, it could not be determined where the nickel ends and the steel begins, but of course the outside is mostly nickel and the inside steel. The nickel is welded to both sides of a sheet of steel. It makes a non-oxidizable article having the stiffness of ordinary steel, and convenient for various uses.

Mr. Mixer pointed out that the small percentage of nickel used in steel is not likely to increase the demand for nickel so much as is generally thought. The Edgar Thompson people had received from Commodore Folger a bar of nickel steel containing 25 per cent of nickel. It was about two inches in diameter and very tough, and a steel chisel was ruined trying to cut through it. It took a beautiful polish. It is obvious that for many purposes a steel with a high percentage of nickel may prove very valuable.

SINKING PILES WITH WATER JETS.—*Genie Civil* thus describes the sinking of iron piles in Chili with a water-jet: Some of the piles were 14.76 inches in diameter, with a flat bottom-flange or pedestal 41.92 inches in diameter, and were sunk to a depth of 28 feet below the bottom of the river through very coarse, compact sand, in which screw piles penetrated with great difficulty, and sharp piles could only be driven from 11.8 to 14.1 feet. A pump delivering about 12,000 gallons per hour through a 4.92 inch pipe would sink two piles, each having a 2.05-inch pipe projecting about 7.87 inches below its base with a 5.9-inch opening. The pile being put in position and the water-jet started, it sank nearly three feet by its own weight, after which it is worked down by means of an endless cable leading from the drum of a hoisting-engine around a horizontal pulley bolted on to the pile so as to revolve the latter about its vertical axis. An average of 18 hours was required to sink each pile. On one side of the river a double-action Worthington pump was used, and on the other a Tangye pump.

MACHINE TOOLS.—In no branch of the applied arts, says the *American Machinist*, has greater skill been shown than in the construction of machine tools. In no country in the world has that skill shown a greater development than in America. It does not follow from this that we say make better machine tools than are made elsewhere, but it is a fact that no tools have been copied so extensively in foreign countries as American tools have been copied. This may not be much to say, but it does follow from this that we are doing work here which is favorably thought of elsewhere. American manufacturers are sometimes slightly jealous of the copying of their tools in foreign countries. We think that it is a credit to them that they are so copied. We are always glad to know that somebody somewhere in Europe is trying to produce a tool as made in America, and at the same time we have little fear that they will be able to beat the American manufacturer on his own ground.

OUR production of pig iron for 1892 was not far from 9,140,000 gross tons (actually 9,138,826 tons), the largest production, with the exception of 1890, in our history. In 1891 our production was 8,279,870 gross tons. This indicates a production in 1892 but little less (some 50,000 to 60,000 tons) than in 1890, and over 800,000 tons more than in 1891.

Scientific Progress.

The Conductivity of Insulating Bodies.

The effect of the physical condition of substances upon their dielectric properties is one that is deserving of more study than it seems to have received. In the *Philosophical Magazine* M. Edward Branley, M. D., calls attention to the fact that very thin fibers of insulating bodies seem to become conducting, and that good conducting material opposes great resistance to the passage of a current when inserted in its path in a pulverulent condition. Thus far there is nothing in his statements that might not have been arrived at by *a priori* reasoning; but that the conductivity of the pulverulent mass may be measurably restored by the discharge of a Leyden jar in the vicinity and destroyed again by a slight mechanical shock, while not new, could scarcely have been anticipated by theory. The phenomena having been demonstrated, however, one or two theories at once suggest themselves as plausible explanations of their cause. There are one or two other phenomena of thin fibers or pulverulent dielectrics, however, whose explanation is not so obvious. For instance, if the two ends of a circuit be varnished with shellac, and after the latter is thoroughly dry be brought into intimate contact, the insulation against low potentials is practically perfect. But place this junction in an atmosphere of pure hydrogen gas, the resistance is gradually lowered until comparatively good conductivity is established, only to be destroyed again equally gradually when the hydrogen is removed.

Neither mechanical shocks nor moderate increase of temperature seem to have any perceptible effect upon the rise or subsidence of conductivity. But if the treatment with hydrogen be repeated after complete resumption of the insulating state in air, the junction cannot be restored to the same degree of conductivity it was made to assume in the first instance, and the effect of the hydrogen gradually decreases with each subsequent application, until it seems to disappear entirely. Carbonic oxide and artificial marsh gas produce the same effect, though to a less degree, while natural marsh gas seems to be inert. The presence of carbonic acid, nitrogen, oxygen or other electro-negative gases, even in considerable proportion with the hydrogen, seem to have no effect upon the phenomena except what might be reasonably attributable to the dilution caused by their presence. On the other hand, if finely-pulverized hard glass be imbedded in the two ends of the circuit and they be brought together again as before, and hydrogen applied, a much higher conductivity will be attained than in the case where shellac was the dielectric, but it will not be assumed gradually as before, but in a series of impulses each succeeded by a non-conducting state, these electric impulses becoming more and more frequent until the current finally passes continuously with nearly the same freedom as it would were the conductor unbroken. On removing the hydrogen, the junction remains conducting much longer than where shellac is used, but loses its conductivity completely and instantaneously. Thus many substances have been tried with similar results, but differing in degree. But the manner of assuming conductivity and of losing it again seems to differ with each, and to be in a measure characteristic of the substance employed. A satisfactory explanation of these phenomena has not yet been suggested.—*Electrical World*.

Electrification of the Steam Jet.

At a recent meeting of the Royal Society, Mr. John Aitken read a paper "On some Phenomena Connected with Cloudy Condensation," which contains the results of some very interesting observations made by him. It was shown that the mere presence of an electrified body in the vicinity has no influence on the steam jet. In order to produce the increased density the water particles in the jet must be electrified, either by direct discharge or by an inductive discharge, effected by means of either a point or a flame. The increased density produced by electrification is due to an increase in the number of water particles in the jet, by the electrification preventing the small drops from coming into contact, by the mutual repulsion it produces, in the same manner as the water drops in Lord Rayleigh's experiments with water jets, which scatter more when electrified than when not electrified. The coalescence of the drops in water jets takes place only under the disturbance produced by the presence of an electrified body, while such a disturbance produces no effect on steam jets. Other experiments point to the conclusion that the increase in the den-

sity is due to an increase in the number, and not to an increase of the size, of the drops. For instance, if steam is blown into a receiver full of air in which there are many dusty particles to serve as nuclei of condensation, the clouding is dense; and if there are few nuclei the clouding is not dense. The same statement holds good for the clouding produced by expanding moist air. If many dust particles be present, the clouding is dense; if few, it is not dense. The explanation of the effect of electrification seems to be, that, since the particles in the jet are in rapid motion, there are frequent collisions among them under ordinary circumstances, and a consequent coalescence of the small drops into larger ones; whereas, when the small drops are electrified, they repel one another, and coalescence is in some degree prevented. The jet, upon becoming dense, emits a peculiar sound, which is the same whatever be the cause of the increased density. But when it is electrified, along with this sound there is another, due to the discharge of the electricity, which causes the electrified jet to appear to make a louder noise.

Geographical Variation in Birds.

Lynds Jones of Oberlin, Ohio, writes to *Science* as follows:

In ornithology, geography is the father of trinomial nomenclature. Climate is one great factor in variation, and topography has not a little to do with making the climate; but geography is unquestionably the cause of variable climate, else would the polar regions be tropical instead of frigid. Topography is at best local.

The variations of a species of birds, which make of it several subspecies, are due to its geographical distribution. These varying individuals do not take the name of "forms," as in entomology, but are set apart as true subspecies, each with a more or less well-defined habitat of its own. But there is a serious difficulty in ascribing any sharp line of difference between the forms which intergrade on the outskirts of the geographical range and a corresponding difficulty in ascribing any definite geographical limit. It is not seldom that individuals of one subspecies are found far within the range of another subspecies.

It is a little singular that certain species do not vary—species which are not only found from ocean to ocean in North America, but which are nearly or quite cosmopolitan. Why this should be true of some species and not of others is still an open question. If the scorching sun of the desert regions will bleach out one species, why will it not do the same for another? The plea of adaptation of coloration for protection cannot be urged here.

Not only are colors affected, but size as well, by geographical position. This is probably more marked north and south than east and west; and yet the variation in size alone is not sufficient for a subspecific division. It is not at all strange that those individuals of a migratory species which push farthest north should possess stronger bones and muscles, and so be larger than those which were not able to fly so far. It would seem natural that the constant recurrence of such a difference would tend, in time, to form a race peculiar enough to be recognized as a subspecies. But it has not proven true thus far in the history of the world, and why should there be any change under the same conditions?

THE RAVAGES OF CHOLERA.—The discovery of a method that would protect an individual from cholera would be of great usefulness, for in India, the home of that disease, the average annual mortality therefrom in the cities is 3.32, and in the country 1.32 per 1000 living. The army statistics show that 2.49 per cent of the European soldiers are admitted to the hospital for cholera, while only 0.95 per cent of the native soldiers are admitted for the disease; but the mortality, 33.69 per cent for the former, 35.5 per cent for the latter, is almost equal. In the various epidemic manifestations of cholera in various parts of the world the mortality has often exceeded 50 per cent of those attacked. In 1884 and 1885 cholera was epidemic in Southern Europe, and in Spain in the latter year the official report states that there were almost 120,000 deaths. There were 51 persons affected in each 1000 living, and the mortality was 36 per cent. These statistics stimulated investigators to attempt to solve the problem of affording immunity to cholera.—From *Protective Inoculation for Cholera*, by Dr. S. T. Armstrong, in the *Popular Science Monthly*.

The total production of white lead in the world is about 650,000 tons per annum, of which the United States produces about one-third.

The Best Mining District
On the Pacific Coast I
GRASS VALLEY, CAL.

THE BEST NEWSPAPER published in the district is
THE TIDINGS.

Daily and Weekly edition. Gives all the Mining News. Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe.

Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation.

DAILY, \$4.00 a year; WEEKLY, \$2.50, in advance.

Machines of all kinds Made and Repaired.
Orders Solicited.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E., 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$3, coin, postage free. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Electricity.

Power Transmission.

The marked success of the experimental test in Germany of long-distance power transmission by means of high tension alternating currents has added a new stimulus to progress in alternating current motors, and during the past year a number of types have been brought out, some of which aim at the solution of the problem of distribution of alternating currents by producing a motor designed to work with a simple alternating current, and others of which are of a polyphase character, provided with a closed circuit armature, such as were used in the Frankfort plant. It seems, says the *Electrical Review*, that some form of efficient alternating current motor is necessary for the utilization of power when transmitted over long distances. Direct current transmission, as the art now stands, is barred, owing to danger to the insulation and commutators if high tension be used, and is barred by the excessive cost of the conducting-mains, if a low tension be relied upon. In the experiments in Germany an efficiency of 74 per cent between the axle of the turbine and the motor was realized. This, however, did not take into consideration losses in the motor. The latter, however, was very efficient, though probably did not realize as high an efficiency as is possible with synchronous motors. The losses in the transformers were very slight, and the line loss was only six per cent for a distance of 110 miles. These favorable circumstances marked out the alternating current as the agency par excellence for distribution at long distances. One of the types of motor developed during the past year was the Stanley-Kelly motor, which is designed to be operated by a single-phase alternating current, the lag due to self-induction being taken out of the field-magnet by means of condensers, which have the property of giving a lead, and thus the lag created by self-induction in the field-magnet is counteracted. These motors have not yet gone into practical use, but if the promises made by their promoters are realized, they will doubtless meet with a large share of success. Other types of alternating current motors have been developed during the past year by Bradley and others, who were early at work in this field. Mr. Bradley is one of the pioneers in the art of triphase transmission, which was the type of system adopted in Germany. It is probable that the polyphase system of transmission and some form of polyphase motor will be adopted in the plant now in course of construction at Niagara Falls. Whether the system will be based upon inventions developed in this country or upon those which have been exploited abroad, it is impossible at the present writing to say. The gigantic character of the undertaking at Niagara Falls lends great interest to that enterprise. The turbines on the American side will be capable of delivering 125,000 effective horsepower by water passing through a tunnel 6700 feet in length. It is expected that power will be furnished at this plant about the end of March, 1893. The rates announced for power are \$10 per horsepower for 5000 horsepower or over; \$10.50 for 4500 horsepower; \$11 for 4000 horsepower, and so on to \$21 for 300 horsepower, all for 24-hour power if wanted, the cost of ordinary steampower for a ten hour day ranging from \$25 to \$40. It is prophesied that all this power will be used up in local manufacturing establishments. Plans are also afoot to erect a plant on the Canadian side of the Falls and to utilize it in the operation of a number of railways extending for a distance of 25 to 60 miles, the towns and cities in the neighborhood being lighted by the system. The Canadian plant is intended to be operated on the polyphase plan with 25,000 volts.

GENERATING POWER WITHOUT STEAM.

Dr. Nansen's late lecture before the British Geographical Society bristled with ingenious devices for passing away the time during which he expects to be icebound and to drift with the floes toward the much-sought pole. So many of these devices are dependent on the supply of electric current that henceforth no well-equipped arctic expedition will be considered complete without its dynamo. It is easy to imagine how cheering will be the effect of the electric light on those whose perilous task will subject them for some months to almost total darkness. Dr. Nansen's proposed method of generating electricity is at all events original, although somewhat deficient in the quality of reliability. He proposes to have a windmill on deck to drive the dynamo, and when the wind fails to let his men take turn about at a "walkmill," in order to afford them such

salutary exercise as might be involved in heaving imaginary anchors. If this method of generating current should prove effective it is but natural to believe that it will hasten the general adaptation of treadmills in prisons to the generation of electricity.

TOMMASSI'S ACCUMULATOR.—This secondary battery consists of elements made up of tubes of lead, or rigid insulating material, such as celluloid pierced with numerous holes to admit the electrolyte. Each tube has a lead connecting wire down its center, making contact with the active material which occupies the rest of the tube. The inventor, Dr. Donato Tommassi, of Paris, claims that this arrangement gives a much larger capacity per pound of total weight. It also reduces the volume of the cells. The following particulars have been given us by the inventor: Charging current, two and one-quarter to two and three-quarters amperes per pound weight of electrode; discharge current, up to one and three-quarters amperes per pound, down to electromotive force of 1.7 volts. The cells can give as much as three and one-half amperes per pound on emergency; capacity, nine ampere hours per pound of electrode; Coulomb efficiency, 95 per cent; Joule efficiency, 80 per cent. M. Tommassi claims that his accumulator has from three to six times the capacity of the ordinary accumulators, weight for weight. If the accumulators turn out as well in commercial use as in Dr. Tommassi's laboratory—as we trust may be the case—they will be a great advance beyond present practice. A company with £9000 capital has been formed to manufacture these accumulators. We may add that we are not very sanguine about this accumulator, as the principle is some decades old; but Dr. Tommassi may have improved the details enough to obtain the excellent results claimed.—*London Industries.*

STORAGE BATTERY.—For the past several days a car operated by the Woodward storage battery has been doing daily service on the Jefferson street car line, in Detroit, taking and holding its position without a single break in the regular service of that route, and doing a 10-trip (or 70 miles) stint between early morning and 7 o'clock in the evening each day. This has been done side by side with the trolley-cars, taking traffic just as it developed, carrying as high as 85 passengers at a load, and starting and stopping wherever and as often as required by patrons of the road. This exhibit has been made as the beginning of an effort to demonstrate beyond peradventure the commercial value of this storage battery. That the car did each day's work absolutely on time at every point of each trip; that, as compared with trolley-cars, it was almost noiseless and remarkably smooth and comfortable as a vehicle, and that it was in every way superior to the trolley-car are facts apparent on the surface to the most casual observer. It is claimed to be much cheaper than the trolley system, and to discount horses.—*Chicago Journal of Commerce.*

COMPARED WITH GAS.—It is satisfactory to note that even in England, where the electric light has been so unfortunately retarded by legal restrictions, the facilities for procuring current are so rapidly increasing as to make the electric light preferable for almost all purposes, and particularly on the ground of economy to any other method of lighting. Mr. Preece, the electrician and engineer of the postoffice, states that its production is much cheaper than gas. Mr. Preece's report shows that the cost of gas is increasing, while, on the other hand, the price of producing electrical energy is declining. Patents are expiring, experience is growing, manufacturing competition is calculated to contribute to this end, and its growing adoption has an appreciable effect in the reduction of prices. Having dwelt on the obligations of large corporations to assure the supply of pure light as a means of sanitation and eradicating disease, Mr. Preece repudiated the erroneous belief that the electric light was only a luxury for the wealthy, and submitted some useful information in support of his statement that the time was not far distant when the electric light would be available to the poorest citizen.

The wonderful results attained in the employment of electricity for welding have done a great deal to elevate the blacksmith. Many heretofore impossible pieces of welding are now done with the greatest ease. Well has the real inventor of this process fulfilled his part in life, and were he to do nothing else, by giving to the world a process so generally useful, he would have done more than his share.

Useful Information.

VULCANIZED INDIA RUBBER.—An investigation has recently been conducted by Lieut. L. Vladimiroff at the St. Petersburg Technical Institute, says a foreign exchange, with a view to establishing rules or tests whereby the quality of vulcanized india rubber may be efficiently judged. It is a notorious fact that no method of chemical analysis gives reliable results for this substance; hence the tests applied were chiefly of a physical nature. From a lengthy series of experiments the following conclusions were deducted, namely: 1. India rubber should not give the least sign of superficial cracking when bent to an angle of 180 degrees after five hours of exposure in a closed air bath to a temperature of 125 degrees Centigrade. The test pieces should be six centimeters thick. 2. Rubber that does not contain more than half its weight of metallic oxides should stretch to five times its length without breaking. 3. Caoutchouc, free from all foreign matter except the sulphur used in vulcanizing it, should stretch at least seven times its length before rupture. 4. The extension measured immediately after rupture has taken place, should not exceed 12 per cent of the original length of the test-piece of rubber. The test-piece should be from 3 to 12 mm. long, 3 cm. wide, and not more than 6 mm. thick. 5. Softness may be determined by measuring the percentage of ash formed on incineration; it may form the basis for deciding between different grades of rubber for certain purposes. 6. The vulcanized rubber should not harden under the influence of cold temperature. These conclusions are to serve in the establishment of rules governing the introduction of vulcanized rubber into the Russian navy.

STREET CAR GAS MOTOR.—It has been decided to use the Connelly Street Car Gas Motor on three of the cross-town lines of the Chicago systems. The first of these motors, says the *News Record*, stands almost ready for the rails in the company's shop in Clinton street. It is a simple piece of mechanism, comprising a vertical gas engine furnished with a heavy fly wheel on one side and a friction disk on the other, all mounted on an enclosed 4-wheel car truck. The motor will develop 10 h. p., and will be run with Pintsch or natural gas, preferably the latter, the gas stored in tanks either at the sides or under the roof of the car. Unlike most gas motors, the piston receives an impulse at every revolution, using 7 parts of air to one part of gas for the explosive agent. Toothed gears are dispensed with altogether, power being transmitted to the car axle by a link belt. A shifting lever throws the driven friction wheel across the entire face of the driver, so that in starting great power with low speed is secured to be gradually changed to high speed and of course less power as headway is made. The motor will be noiseless, able to pull 3 loaded trailers and can climb a 6 per cent. with ease. It is considered a strong probability that this gas motor will be substituted for horses on all horse car lines of the north and west sides.

VENTILATING A TUNNEL.—The Pennsylvania Railroad Company is now ventilating its tunnel through Baltimore by fans driven by electric motors, the current being transmitted from a powerhouse situated near the North avenue end of the Bolton yard. A ventilating stack and fan have been erected over the northern section. The current for the operation of the fans is conducted through the tunnel to the ventilating shafts. Arrangement is also made to light the tunnel by electricity. The ventilation is accomplished by means of a slanting subway eight feet wide by sixteen feet high from the side of the tunnel, near its top, to the foot of the ventilating stack, which, on account of the heavy foundation necessary, is located at the side of the tunnel. At the foot of the shaft a large fan, fashioned like the blades of a steamboat propeller, revolves on a vertical shaft, forcing a strong upward draft. The vacuum created at the middle of the tunnel causes the smoke and gas to be drawn from the end of the tunnel to the center, and out the top of the stack. The stacks are 100 feet high and 18 feet square. Adjoining each stack there is a small ornamental brick house for the storage of oil and materials used in operating the system. By this system the tunnel is cleared of smoke and gas in less than two minutes after the passage of a train.

The gross earnings of the railroads of the country last year are estimated by the statistician of the Interstate Commerce Commission at \$1,222,711,693, an increase of \$125,950,303 over the earn-

ings of 1891. The operating expenses were \$814,722,082, an increase of \$82,834,109, which leaves an increase in net earnings of \$43,116,114.

COAL was hardly used at all 350 years ago, remarks Mr. J. E. Taylor, F. L. S. Yet since then Great Britain has consumed nearly half the stock deposited by nature in its coal cellars many millions of years ago. At the present rate of increase in consumption what will be the condition of those cellars after another 350 years? It is clearly indicated that this period will witness a marvelous development of the economic science. Coal, long before that, as a form of energy will be regarded as a somewhat antique and worked-out material. The ebbing and flowing tides, the shifting winds, the waters running to the ocean, perhaps even volcanic and earthquake energy, will have taken its place. Indeed, a line of inquiry and research now going on may possibly affect the commercial interests of the whole world within the short space of the next five years. This relates to the use of petroleum, already being tried on steamers and locomotives of the Caspian sea and vicinity. The coal fields of the world will certainly be worked out within an historically brief period, but a distinguished Russian chemist finds grounds for believing that petroleum is still being formed by the action of water on heated metallic deposits, and that the supply will be permanent.

THE ALUMINUM DECISION.—A decision rendered by the United States Circuit court, northern district of Ohio, eastern division, on Wednesday, is of no little importance to the aluminum trade. By this decision the litigation between the Pittsburgh Reduction Company and the Cowles Electric Smelting and Aluminum Company, of Lockport, N. Y., closes in a victory for the former. Two years ago the Pittsburgh concern entered suit against the Cowles Company for infringement on a base patent on the process of dissolving alumina in fluorides and passing a current of electricity through the mass, thus producing aluminum. This is the only aluminum process which has proved a commercial success. Judge Taft decided in favor of the complainant on every point, thus giving the Pittsburgh Company the exclusive right to the only aluminum process which has been successful commercially. The case was stubbornly fought on both sides, and the Pittsburgh Reduction Company deserves credit for the vigorous manner in which it has defended its claims.—*American Manufacturer.*

THE CORROSION OF ALUMINUM.—Among the many fictions which have been disseminated concerning aluminum, says the *London Electrical Review*, is that of its incorrodibility by sulphuric and nitric acids, whether dilute or concentrated; this statement has, strange to say, been subscribed to by such eminent authorities as Deville, Wustz, Hunt, Langly and Roscoe, whom, it must be presumed, did not use the pure metal in their experiments. Mons. G. A. LeRoy, having been induced to study the possibility of replacing lead and platinum by aluminum in various manufactures, has been surprised to find that the statement of these authorities is entirely incorrect on this point. Experiments made with four different samples of aluminum, the composition of which is stated, two of them being made by Deville's process at the old Nautern Works by Messrs. P. Tronin & Co., show that the pure metal is so rapidly attacked by strong nitric and sulphuric acids, even in the cold, as to be quite unfit for use in the manufactures or processes in which these acids take any part.

CHROMIUM BY ELECTROLYSIS.—In a recent issue of the *Comptes Rendus*, of the Paris Academy of Sciences, M. Em. Placet describes a new method of preparing chromium by electrolysis. An aqueous solution of chrome alum is first made, to which is added an alkaline sulphate and a little sulphuric acid, and a current is then passed through the solution. Pure chromium is then deposited at the negative pole. Thus prepared, the metal is of a bluish-white color and very hard. It resists atmospheric influences, and is not attacked by concentrated sulphuric acid, by nitric acid, or by a concentrated solution of caustic potash. It is proposed to carry chrome-plating on an industrial scale to replace the nickel plating. Good adherent deposits of chromium have been obtained from the same bath on brass, gun-metal, copper, and even on iron. The deposit is said to resemble oxidized silver. An ingot of the pure metal, weighing one pound, has been prepared and sent to the Academy by the inventor of the process, who is now engaged in investigating various alloys of the metal.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the edges and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Calaveras Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for Twelve Months. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 80 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

HECTOR.—Amador Record, Jan. 19: Foreman G. T. Taylor informs a Record reporter that the Hector mine is now cleared of water to the 900 level. It has been a long and tedious job to hoist the immense body of water from the old workings, as the Lincoln mine to the north virtually drains its surplus into the Hector shaft. Mr. Taylor undoubtedly feels that he is entitled to some credit, as his own company had some doubts of his being able to clear the mine at this season of the year with the imperfect appliances—double skips—now in use for hoisting water. It is contemplated very soon to replace the skips by an improved pumping plant. The company, as well as the chief manager, Mr. Valentine, are entitled to great credit for the perseverance they have so far shown in opening up this magnificent property. It is proposed, now that the 900 level is clear of water, to thoroughly explore it, and in the meantime to probably go another 100 feet, so as to be ready for all contingencies. Within the next week or two the 40 stamps of the mill will be pounding away on surface rock taken from the upper levels. This will be continued until the 900 level is explored and can turn out sufficient rock to feed the mill. The Hector mine is on the mother lode and adjoins the Wildman on the north, and the Lincoln lies still north of the Hector; and, by the way, that Lincoln mine is an eye-sore to the people of this section, just because a Scotch and American company own the stock and are locking horns over some imaginary trouble about the management of the mine. Our local mining sharps cannot understand just why this splendid property is lying idle. There is another mine on the mother lode, north and east of the Lincoln, that the Record wants to say something about, viz., the Belmont. Superintendent Tibbitts has done as much work for the money as has ever been done in this section, and the whole of it has been virtually thrown away through the parsimony of the directors of the company he represents. Let it be understood that Mr. Tibbitts and no other managers for eastern companies ever say anything about their properties. The fact is, they are afraid to. What the Record gives is common local talk by mining men in the immediate locality. The fact is, all eastern companies appoint a superintendent for their properties, and then hemper him in every way, and expect him under these conditions to do impossible things. But never mind; the Belmont has a great future before it, and with proper appliances, proper machinery, and with some liberty of action to its superintendent, Mr. Tibbitts, it will prove itself to be one of the great mines of the mother lode. The mine needs pumps instead of skips for raising water, for all the humbugs that were ever tried for hoisting purposes and waste of money, the "skip" can take the "cake." It is generally understood that the Belmont Co. will this spring put in a new plant on their property. It certainly needs it, if successful and economical work is to be done.

MINING EXCITEMENT IN IONE.—Amador Dispatch, Jan. 21: Quite a ripple of excitement was created among the people of Ione a few days ago by the discovery of a very rich quartz ledge a short distance above the new Preston school-building, on Mrs. Mullen's ranch. Some of the rock which was tested is reported to be almost fabulous in richness. In consequence of this unexpected discovery, a large number of the citizens visited the place last Sunday, notwithstanding the heavy rainstorm that was prevailing at the time. It is not yet known how extensive the ledge is, as it was only the top rock that was prospected.

BAY STATE.—Amador Record, Jan. 19: The new pump put in at the Bay State mine by Knight & Co. is taking the water out of the shaft at a lively rate, and Superintendent Jones is well pleased with it. Dr. Boyson, of San Francisco, is now in Plymouth, looking after his mining interests. He has the Bawden claim bonded and has sunk a shaft 45 feet, and is now crosscutting for the vein. He will remain in Plymouth until the ledge is encountered. The doctor has extensive mining interests in Amador and is not backward in asserting that this is the banner quartz-mining county in the State. At the South Enreka mine they are preparing to sink. The water being so strong, it would be impossible to sink without controlling it in some way, and in order to save the purchase of a pump, the superintendent, J. F. Parks, has constructed a bulkhead in the east crosscut, thus holding the water at the 500-foot level until such time as is seen fit to tap the same and draw the water off. A bulkhead has never yet been tried by any of the mines in this section, but we are informed has been successfully employed in other mining districts. If successful in the South Enreka, and we can see no reason why it should not be, it will no doubt be used by other mines to successfully handle their water when sinking. Foreman Riley is now having the sump cleaned out, and sinking will be commenced at once and continued for 300 feet, and from present indications at the 500 level, this mine will soon be placed on our bullion-producing list. At the Wildman mine they are progressing very rapidly in sinking to a lower level and are now within one or two sets of timbers from the 1000 level, the 100 feet having been sunk in less than four weeks. Superintendent John Tregloan feels very proud over the result. Mining men say that it is the most rapid sinking ever done in this district on the mother lode. Mr. Tregloan attributes a good

deal of this success to the splendid body of men he has in his employ and to the facilities in having good pumps with which to handle the water. The superintendent intends to continue sinking another 100 feet, unless stopped by the directors of his company. The advantages in having two or more levels to work on are manifold in even inexperienced miners. In the opinion of the Record, and some of our very best informed mining men, Mr. Tregloan's company will show the part of wisdom if they permit him to work the mine in his own way. The expenses would be lowered, in proportion to the output, and the general prosperity of the mine largely increased.

Butte.

AT THE PHOENIX.—Oroville Mercury, Jan. 23: Dr. T. W. Serviss, Dr. F. W. Gibson, L. E. Norton and a Mercury reporter were a party of four that left Oroville yesterday morning to visit the Phoenix quartz mine, near Hurlston. The party was also accompanied by Dr. Bebee of Kansas. The Phoenix is situated about 24 miles from Hurlston, to the southeast, and is a lode that has for years been famous for its richness in free gold, many thousand dollars having been extracted from it by primitive means. It is only since its acquisition by the present company that any efforts have been made to work it upon a large scale. It is now under the immediate superintendency of George S. Colmen, a miner of long experience in Colorado and Central America. He has now a crew of men sinking upon the lode, and a depth of 105 feet has now been reached. From this point levels will be run north and south and sinking continued. The ledge is from 6 to 12 feet wide, and carries a heavy percentage of high-grade sulphurets. The rock also runs very high in free gold, and repeated panning by the party yesterday from the dump showed, without exception, almost marvelous prospects. New buildings for the miners, a shaft-house and new mill, are in course of erection, and within 30 days Mr. Colmen expects that the Phoenix will be adding to the gold output of the county. The sulphurets will be all concentrated, and for the present shipped to reduction works for treatment. The mine is situated upon a bold ridge of the Sierras, at an elevation of 1776 feet, and from the buildings a magnificent view of the Coast Range, Lassen Buttes, Marysville Buttes and the whole Sacramento valley is obtained.

Calaveras.

WEST POINT DISTRICT.—Cor. Calaveras Chronicle, Jan. 21: At the Cleveland mine, situated on the south bank of the Mokelumne river, and owned by Mitchell & Co., they are taking out ore that will go \$30 per ton. The Williams mine, Trappiener & Co., owners, are also taking out good rock. At the Comet mine, owned by Larson & Co., they are at present taking out ore that will go \$100 per ton, while Paddock & Co. are also extracting some good-looking ore from their mine. Nixon & Co. are busily at work on their property. The rock from this mine, at the last run of the mill, paid over \$100 per ton. Gibson & Co. are taking out some fine ore from their mine at Sandy gulch, as are also Bardsley & Herbert. Chick & Loyd are at work on their mine, and the prospects are flattering. Mr. B. Carlton has quite a number of tons of ore on the dump ready to crush. The Blazing Star mine is still keeping the water out and will commence work again when everything is arranged satisfactorily. The Riverside Co. are also arranging their affairs, and will resume operations shortly. The Scorpion has resumed operations under the management of Mr. M. Dennison, and we look forward to good returns from this property. The Keltz mine, owned by Peasley & Co., recently crushed ten tons of ore that yielded \$60 per ton. Jenkins & Co. are working along on the Barnes, Billy Williams and Henry mines. The Morning Star mine, the north extension of the Henry mine, has been swallowed up by a homestead patent, and that is the way a great many of the localities are going—like an auction—going, going, gone! The North Star mine is still in the land of the living, and will "get there" before long, while the Lockwood is still quietly resting on its reputation. The Lone Star and Reed & Hillery mines are parallel veins running nearly north and south, from 100 to 150 feet apart. They are situated on the North fork of the Mokelumne river, about four miles westerly from the village of West Point. The lodes are worked by tunnels, one of which is on the lode all the way for a distance of 1300 feet, and is called the prospect tunnel, and you can rest assured that it is a fine piece of work. I took some samples of the ore from the end, or the face, and they were rich. At a distance of 1300 feet under the mountain we would be at a perpendicular depth of about 400 feet. The two mines are connected at intervals by cross-tunnels, which give a good ventilation. There are nine or ten tunnels run in from the mountain-side on these lodes, and they are all connected, the one with the other, by winzes or chutes sunk on the lodes at intervals for the double purpose of giving good ore and also to facilitate the extraction of the ore. The veins or lodes in some places were 10 and 12 feet wide, but I think they will average all the way through on both lodes about five feet. There are about 1000 tons of ore at present in the different chutes ready for the mill, which is 20 stamps and is kept running day and night. The sulphurets are concentrated on blankets and worked by a pan. The drills are run by compressed air, which is supplied by three compressors; the forges and blacksmith shops are all supplied with compressed air, and the compressors are run by waterpower from a height of 300 feet above. The Lone Star Company own the West Point ditch, and therefore have all the power they wish, either to run the drills by air or electricity. The mill is also run by waterpower, and it is situated so that whichever way or tunnel the rock may come from the mine, it finds its way on a properly constructed track

to the mill. Even at the lower tunnel, which is 25 feet from the river-bed, the rock is brought out and hoisted up to the crusher in the mill by the same waterpower that runs the mill. The mill, I should judge, will crush about 30 tons per day. The output of the mine, of course, is a great deal more, but it is kept in chutes in the mine, which when full will allow of further prospecting. I think that the mine is good for many years yet as a producing mine, and, judging from the looks of the ore, a paying one also. Of course some of the rock runs over \$100 per ton, but the general average would be about \$18 per ton, which is plenty high enough to make it a paying investment.

El Dorado.

SLATE.—El Dorado Democrat, Jan. 21: A number of improvements have been recently made at the California slate quarry since it has changed hands. A channeling machine has been put in for cutting out slate in blocks, saving a great waste of material which necessarily resulted from the blasting process. An air compressor is being negotiated for to drive the machinery, new buildings are going up, and an air of business prosperity hovers over the premises.

Nevada.

BRUNSWICK MINE.—Grass Valley Telegraph, Jan. 23: Supt. W. A. Hawley informs us that everything is working to a nicety out at the Brunswick mine. The shaft is being put down deeper, and the water is easily handled. The ground is tolerably good considering what they have gone through. A station is now being cut at the 700 level, and drifts will be run east and west as soon as the station is completed.

BEN FRANKLIN MINE.—The Ben Franklin mine is located at the western foot of Osborn Hill, and is owned by Michael White and sons. There is a tunnel in the hill about 150 feet in length, and there is a ledge nearly all the way that averages about 10 inches in thickness. A crushing from the Ben Franklin has just been completed, and the result was \$33 per load. There were 12 loads crushed.

THE PROVIDENCE MINE.—Nevada Transcript, Jan. 23: The old Providence mine is now assuming its pristine glory. The mine is looking splendid, and from present appearances bids fair to outrival all former outputs of the precious metal. The ledge now being worked is very large, and is paying handsomely. There are about 50 men employed in the mine, and a few more have been engaged to go on next week. Twenty of the forty stamps are being run night and day, and in three or four days ten more will be started up, and it will not be long before the other ten will be pounding away for an indefinite time. The new owners are very proud of their mine, and are confident that they have one of the very best in this district. The mine has been opened up under the superintendence of Carl Davis, who is regarded as one of the best quartz miners in the State.

HUNSON BAY MINE.—Transcript, Jan. 21: Work has been going on quietly but steadily and firmly at the Hudson Bay mine for some time past, and now the shaft is down 142 feet. The rock has heretofore been very hard, but in the past day or two it has been getting better, and yesterday a beautiful quartz stringer was found in the bottom of the shaft. Mr. Alf. Tregidgo brought some of the rock, taken from the stringer, to town, and it is of the very best quality. The stringer is a large one, and from the indications we would not be surprised to hear of the ledge being tapped at any hour. The water is being easily handled, and work is being pushed ahead to the greatest advantage. The Hudson Bay joins the North Star on the north, and the whole surrounding country is famous for its rich ore veins.

San Diego.

THE LOST PEGLEG.—San Francisco Chronicle, Jan. 22: Another party of prospectors has left this city in search of the famous lost Pegleg gold mine, which exists somewhere in the Colorado desert between Yuma and Los Angeles. The party is composed of Thos. L. Doran, John D. Bell and Jas. Corcoran. The last two are old mining prospectors and experts. The former, Thos. L. Doran, is now on his third trip in search of the fabulously rich lost mine. Doran's adventures have been published before, and the history of the mine and the many searches made for it have filled es many columns in different newspapers as there are skeletons of the searchers bleaching on the desert. In both of Doran's former trips he nearly lost his life from the hardships he went through, and the last time he was saved by Bell, who was his companion. The members of the party feel that they will be successful this time, as they have secured, after six months' search this summer and fall, a tracing of the exact route followed by Pegleg Smith when he crossed the desert and found the "three little golden hills." The plan of the party is to go to Los Angeles, where they will stay two days, and then proceed to San Bernardino, where they will get their outfit. They will then strike for the desert, through Warner's Pass, where Pegleg Smith ended his wearisome journey. From Warner's Pass they will follow the line traced on the map as closely as they can, but will not proceed more than two days forward before hunting for the "three little golden hills higher than the rest," which they expect will bring them millions of dollars. This will cause the party to explore a more northern part of the desert than Doran has been on before. The party is prepared to make a systematic search for six months before the excessive heat compels them to leave the desert.

Siskiyou.

BLUE GRAVEL.—Yreka Journal, Jan. 23: Lee, Lash & Co., of the Greenhorn blue gravel mine, just south of Yreka city limits, are now tunneling to get on the main channel, as a large boulder was found at the bottom of the new shaft, which must be removed. A good prospect was found at the bottom of the shaft, and good pay is anticipated above the immense

boulder. The new steam pump lately received works fine and keeps the sillage water drained from the claim with the greatest ease. Spencer & Co., of the Siskiyou quartz mine, on the north branch of Cottonwood creek, took out about \$1000 from one week's crushing with a two-stamp mill lately, and are now sinking down on the ledge for the purpose of opening it to better advantage. The ledge averages 24 to 3 feet in width, and appears to be a permanent lode, with quartz enough in sight to yield a large amount of gold, as it is very rich. Water has been turned into the ditches at Quartz Valley and Oro Fino, where hydraulic mining is carried on with good success, to be continued right along until late in the summer, as there is considerable snow on the Salmon range of mountains to afford a good fountain. The cold weather lately interferes with mining to some extent, by freezing up the water supply, so that work cannot be commenced early in the morning, besides hardening the ground for tough digging until after the sun is up awhile.

Shasta.

THE REID MINES CONSOLIDATED.—Redding Free Press, Jan. 21: The Reid Mines Consolidated Company of Old Diggings district own three claims, or 4500 feet of ground, located north and south, and on which there are at least five parallel ledges running in the same direction. To open up and develop these ore bodies is the aim of Col. Stevenson, the president of the company. To do this in a workmanlike manner, Col. Stevenson has commenced at the lowest point by sinking the old Spanish incline shaft to a greater depth. What is known as the Spanish shaft was commenced years ago, and was sunk about 60 feet on very rich free-gold ore, when the ledge appeared to pinch out. The new company, having purchased the property from E. A. Reid and others, miners were set at work in the shaft, and on going a distance of 15 feet, the ledge came in good and strong, the ore assaying quite rich. At present there are three shifts at work, and the shaft is down 110 feet, with a strong ledge of ribbon quartz four feet thick, the ore well mineralized with some free gold, but mostly steel sulphurets. A clay gouge continues with the vein which pitches east, and is considered a good indication. The walls are well defined and composed of metamorphized porphyry, the hanging-wall being partially crystallized. The ore on the dump will average about \$40 to the ton. About 500 feet up the mountain Mr. Stevenson will sink another shaft as soon as the road to the spot selected is completed, which is now well under way. The Spanish shaft will be extended down 500 feet; then from it a level will be run east 300 feet, crosscutting all the ledges at great depth, and from which level a tunnel will be extended on the large ledge and connected at greater depth with the proposed new shaft farther up the mountain, spoken of above. In this way the mine will be opened up in good shape and all the ledges exposed, and to obtain an abundance of ore it will only be necessary to run a series of slopes to the surface. Col. Stevenson thinks, judging from the formation, that at a depth of 500 feet free gold will be encountered in the quartz. Passing over the ridge, we came to the five-stamp mill owned by the company, which was running on rock taken from a tunnel on the east side of the mountain, and which we did not visit. There is only a small batch of ore from this tunnel, and as soon as it is worked ore from the Spanish shaft will be hauled to the mill and tested.

SILVER SHIPMENT.—The Lost Confidence mine, at Iron Mountain, shipped by Wells, Fargo & Co., on Thursday, 20 bers of silver bullion, the shipping value being \$20,000. The bars showed a total of 31,657 ounces. This is the result of their last run, the mine having shut down pending an advance in the price of silver. During the past six months 9000 tons of ore have been handled, giving employment to many men. It seems too bad that the low price of silver has stopped an industry of so much value to this country.

MINING ITEMS.—Wm. G. Hodson, secretary of the Miners' Association, shipped nine boxes and six sacks of ore to San Francisco this week, to be placed on exhibition at the Mechanics' Fair. The Millville Tidings says that Orrin Welsh and Sam Lofton have struck an old river channel on a branch of Cow creek, which promises to be very rich. Frank Panter owns an extension to the Reid Mines Consolidated Company, and is running a tunnel to crosscut the same ledges extending north and south on the company's ground. Being lower down on the hill, he will have good ore-backs. We learn that E. L. Bellou, of Igo, who has recently purchased new machinery, is going to make a success of his plant. Mr. Fitch, who was recently over in that country, says there is much turmoil over the ownership of certain claims, and that claim-jumping is a daily occurrence.

Sonoma.

CHROME.—Sebastopol Times, Jan. 20: The Healdsburg Chrome-Iron Company has received from the Nevada Metallurgical Works of San Francisco the following assay of ore, sent to that establishment: "The piece of ore contains 41.3 oxide of chromium; chrome, 20 per cent." Mr. Hagaman informs us that this is satisfactory to the company, and that work of developing will be commenced at once.

Trinity.

TRINITY RIVER MINES.—Cor. Journal, Jan. 21: The writer left Weaverville in company with Mr. J. R. Flegg on Monday of last week, to whose courtesy he is indebted for a ride to Douglas City, and then down to Hurst & Eliason's claim at Steiner's Flat, which were told has been worked by them since 1874. There are in this property 100 acres patented. Two ditches one-half and one mile long respectively, bringing the water to the mine from Dutton's creek with a pressure of 250 feet; 300 feet of 15

and 11-inch pipe carries the water to the giant which discharges it on the banks, which average 40 feet in height. We are informed that it pays about 10 cents per square foot, and that in an average season they strip about 20,000 feet of bedrock. The early rains enabled them to commence piping at least a month earlier than usual this season. They also own 80 acres of school land, as well as 60 acres more of mineral land. On that portion of their property devoted to agriculture they raise several varieties of apples, pears, peaches, strawberries, raspberries, blackberries, gooseberries, currants, etc., besides an endless variety of vegetables and melons. The day after our arrival there, I was ferried across the river to the Hubbard claim by one of the employees on the ditch and climbed up the hill to the camp. The prevailing opinion seemed to be that it would take about a month longer to put the ditch in condition to enable them to begin piping operations. Passing on down the river about four miles by trail, I reached the Evans' Bar claims of H. H. Carr & Sons, who own 65 acres of good mining ground, two ditches of one-half and three-quarters of a mile each from Skunk creek conveying the water to the two 800-foot strings of 15-inch pipe, at the end of which two giants with nozzles of 5, 6 and 7-inch diameter and 180 feet of pressure discharge the water on the banks of gravel. The sluices are about 300 feet long, paved with blocks 12 inches square. The gold in this property is generally coarse, and the best cleanup made in any season during the five years of the present ownership amounted to a little over \$7000. The upper bench of gravel is very rich, but the owners are working off the lower bench so that the gravel can be used for a dump in the future. The day I was there the bones of an Indian were piped out with a stone pestle, a large seashell and about a hat full of obsidian strips. One of H. H. Carr's sons ferried the writer across the river, where, after climbing up the hill for two or three hundred feet, he struck an old ditch, along which he traveled about half a mile to the Last Chance mine, belonging to Ham & Marsh, who own 31 acres of very rich ground. Last week two pieces of \$8 and \$15 respectively were picked up in the top dirt, which is said to be very rich, one piece of \$47 having been found there last spring. Messrs. Ham & Marsh do not own any water-rights, but have to depend upon the seepage water, and consequently can wash off but very little of the rich ground they own.

NEVADA.

Washoe District.

CON. CALIFORNIA AND VIRGINIA.—Virginia Chronicle, Jan. 21: 1100 level—Have removed the air-pipe and track-rail from this level and suspended prospecting there for the present. 1500 level—We continue running water through the old stopes at different points. Have resumed the extraction of ore and fillings from the south drift where it connects with the old stopes. 1600 level—Are repairing the main south drift and the east crosscut leading therefrom to the upraise connection with the 1500 level, north drift. 1650 level—Have continued making necessary repairs to the drifts on the sill floors of this level. We continue to extract some ore from the old stopes, eight floors up in the upraise, No. 6 carried up from the main north-west drift; also from the old stopes in working north from the crosscut run west from the north-west drift. Have extracted during the week from the 1500 level stopes and 1650 north-west drift openings and raised to the surface 260 tons of ore; average car assay value, \$32.70 per ton.

OPHIR.—1465 level—The upraise started on the sill floor, on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground, 101 feet below the sill floor of this level, has been carried up 12 feet; total height, 86 feet, continuing in porphyry with quartz.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 15 feet; total length, 478 feet; continuing in porphyry and clay formation.

UNION CON.—900 level—The joint Union Con. and Sierra Nevada west drift has been extended during the week 24 feet; total length west of joint shaft, 2845 feet. The face is in porphyry and streaks of clay.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 26 feet; total length, 594 feet; face in porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 24 feet; total distance west of shaft 2845 feet; face in porphyry and clay.

ANNES.—On 420 level north drift from east crosscut No. 1, north, was advanced 18 feet; total, 49 feet; formation, quartz of low assay value.

BEST & BELCHER.—200 level—During the week the north-west drift has been advanced 14 feet, passing through clay and porphyry; total length, 149 feet. 900 level—West crosscut No. 3 has been extended 18 feet through porphyry and seams of clay; total length, 87 feet.

GOULN & CURRY.—200 level: During the past week, west crosscut No. 5, started 432 feet from main west drift, has been advanced 16 feet; total length, 258 feet; face in hard porphyry and stringers of quartz. On the Suto tunnel level the joint north drift with the Savage Co. has been advanced 24 feet; total length, 840 feet; face of drift in hard porphyry.

CHOLLAR.—The north drift from the south line, 550 level, is out 115 feet; face in quartz giving low assays. Are repairing north drift, 750 level, and retimbering the two north compartments of the main shaft. The north drift from the east crosscut, 160 feet south of north line, 930 level, is out 103 feet; face in porphyry and clay. Have discontinued this drift and

from its face started an east crosscut, which is now in 9 feet; face is in porphyry.

HALE & NOBECROSS.—We continue retimbering main shaft above the 600 level. Main Incline—Are making the necessary repairs, and have completed the work of retimbering that portion of the incline between the 1700 and 1800 levels, which required retimbering. 1800 level: West crosscut No. 1 from the main south drift was advanced 20 feet; total length, 55 feet; face in porphyry and quartz. No. 3 west crosscut from main north drift was advanced 17 feet; total length, 252 feet; face in porphyry with streaks of quartz. West crosscut No. 4 from main north drift was advanced 18 feet; total length, 112 feet; face in porphyry with streaks of quartz.

POTOSI.—The south drift from top of raise, 1000 level, is out 45 feet, following a streak of quartz from three to six feet wide, which has narrowed down to 18 inches in the face of the drift, and contains bunches of good ore. Are grading and enlarging the connection between the Potosi winze and the north-west drift, 1800 level Ward shaft. Extracted and sent to the mill the past week 442 tons and 1500 pounds of ore from the 550, 930, 1100 and 1150 levels. Milled during the week 444 tons; on hand at mill, 80 tons, 150 pounds. Average battery assays, \$25. Average car sample assays, \$33.29. Shipped to U. S. Mint, Carson, 299 pounds of crude bullion.

WARD SHAFT.—There has been no work done on the 1800 level of the Alpha and Exchequer during the week. Have been engaged in placing pressure pipe in the shaft. The west crosscut from the north-west drift 300 feet south of north line of Bullion, 1800 level, is out 200 feet; face in low grade quartz and porphyry. Are still enlarging the connection between the Potosi winze and north-west drift, 1800 level.

OCCIDENTAL.—The main north drift, 750 level, has been extended 17 feet; total distance from No. 1 winze 607 feet; face still in low-grade ore. No. 2 winze from south drift, 750 level, is down 11 feet in low-grade ore. East crosscut No. 2 in Zadiq drift, Suto tunnel level, has been advanced 14 feet; total length, 157 feet, and has reached the east wall. No ore of value was found in the crosscut. Have resumed driving the main south drift.

BULLION.—Have started a crosscut east from north drift from top of raise from east crosscut 320 feet of north line, 1300 level. The face is in porphyry and low-grade quartz. The west crosscut from the north-west drift, 300 feet south of north line, 1800 level of Ward shaft, is out 200 feet; face in low-grade quartz and porphyry.

EXCHEQUER.—There has been no work done on the 1800 level during the week. Have been engaged in putting water column in the Ward shaft.

ALPHA.—There has been no work done on the 1800 level during the week. Have been engaged in putting water column in the Ward shaft.

KENTUCK.—During the week we have extracted 12 tons of ore from the 6th and 7th floors above the east crosscut on the 160 level. Car samples average \$39.40 per ton.

NEW YORK.—The west crosscut from the southwest drift from the shaft, 850 level, is out 7 feet; the face is in a mixture of clay and porphyry. Are extracting from 10 to 12 cars of ore per day from the 700 stopes, car samples averaging about \$30 to \$40 per ton. Shipped to the Washoe mill during the past week 167 tons, 922 pounds of ore; milled during the week 167 tons, 922 pounds of ore; on hand at mill, 60 tons; average battery assays, \$34.72; average car sample assays, \$36.70. Shipped to U. S. Mint, Carson, 262 pounds of crude bullion.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 6 feet; total length, 33 feet; the face is in hard porphyry.

Robinson District.

A BLOOMING CAMP.—White Pine News, Jan. 21: Frank Burk, who was in Ely a month ago, has been writing up this section in the Salt Lake Tribune, and to say that he looks at it through rose-colored spectacles is drawing it mild. He says so many good things about Robinson district that it is a difficult matter to make a selection, and we would fain publish the letter entire, but its great length stands in the way. Speaking of the Monarch, owned by R. A. Riepe, he says: "This, according to old miners, is a better-looking proposition than Butte was when the now famous Anaconda was first started." Further, he says: "To understand the great untold resources of this country, a person should visit it and see for himself. I simply give a meager outline of what was seen in a five days' sojourn, where other business seriously interfered with the work of looking up prospects. One thing is certain, that if the long-talked-of railroad comes through the valley here, Ely will far surpass the most sanguine expectations of her warmest admirers."

White Cloud District.

COPPER.—Lovelock News Era, Jan. 20: Ernest V. Clemens, a cousin of Mark Twain, and treasurer of the White Cloud Copper Mining Company, in honor of whom the new town of Clemens has been named, arrived from New York city on Saturday last. He immediately took stage for White Cloud district to inspect the property. This is Mr. Clemens' third or fourth visit. He believes the range of mountains in which the copper mines are situated to be as heavily mineralized as any in the known world. He will return to Lovelock by Saturday and continue on to San Francisco to hasten the shipment of the bucket tramway from the California Wire Works. A two-months' test run of the 40-ton square furnace, which has been erected at Clemens, will be made when the tramway is in position to deliver ore from the mines.

BRITISH COLUMBIA.

OSOYOOS.—Colonist, Jan. 15: The district of Osoyoos has come to the front in a very remarkable way during the past year as a gold-producer. The principal camp is about Fairview, in the vicinity of Rock creek, and embraces the well-known claims of Ratler, Brown Bear, Silver Star and Wymn, acquired by Geo. Atwood and E. D. Reynolds for the Ratler English Milling and Mining Co. These properties were paid for in spot cash, and the direct amount of money transferred in payment for same exceeds any deal hitherto made in the interior of the province. Other very valuable claims exist, among them being the Silver Crown, owned by Messrs. Andrews & Fleming, of Seattle; and Stemwinder, Morning Star, Black Diamond, Wild West, claims by various parties. Camp McKinney, also in the same district, has a good property in the Eureka claim, which is being operated by the Douglass Mining Co., other important claims being Carbonate and Cariboo locations. Boundary creek has some remarkably good prospects, which have been opened up by Mr. Atwood and the Spokane & Great Northern Mining Co. Trial shipments of ore have already been made and proved very high grade. Many varieties of both silver and gold ore occur in this district, the Mineral King and Mountain Chief being free-milling ores. Kettle river and Priest lake have added to the known wealth of the district, and we look for a large development next year. The district of Osoyoos, like West Kootenay, is very easy of approach from the other side of the line and offers great inducements to prospectors, who find their field of operations too circumscribed south of the 49th parallel. The first continuous supply of gold bullion produced from quartz mined in this province promises to come from Osoyoos, which is no mean distinction. Trail creek is advancing steadily in the same direction. The ores from this camp contain as high as 7 per cent copper, but gold is the principal value. Several very important properties are mentioned as promising to make big mines, viz., the Le Roi, Center Star & I. X. L., O. K., Standard, Yellow Jacket, Josie, etc. The Le Roi and Center Star have been opened by tunnels over 200 feet long, and the development of the entire camp has been of the very best character. The future of Trail creek is assured, and as wagon-road connection is now had with Northport, on the Spokane-Northern railway, it is easy of access, which is no unimportant factor in the opening of a camp. A very promising gold find was made on Salmon river late last summer, which gives high average returns in free gold. The country, a small amount of placer gold, has attracted the attention of Nelson men as a possible gold-quartzfield. On Toad mountain and in the district of Nelson no new discoveries have been made, but it already has such properties as the Silver King, Dandy, Iroquois, Goldendale, Poorman, Whitewater and others, upon which a vast amount of work has been done. So far as yet known, the Silver King is without a peer, and when the hope which has been deferred so long is at last realized, this camp will at last take its proper place as a great mining center.

LOWER CALIFORNIA.

THE SAN FERNANDO SOLD.—The San Diego Union is advised of the sale to Denver capitalists of the great San Fernando copper mine in Lower California for \$250,000. Operations will begin at once for the production of copper ore. There is said to be \$75,000 worth of ore on the dumps now ready for smelting. The ore runs from 50 to 55 per cent copper. The mine had been worked on a large scale by Kelly and Woolridge of Mazatlan, who were offered \$1,500,000 for the property as it stood before their desertion of the country to escape capture for wholesale smuggling some years ago, since which time the property has been lying idle. The mine is situated about 100 miles south of San Quintin and 17 miles from the ocean, in a country bearing every indication of mineral richness. Dr. O'Clery, a former owner of the mine by virtue of a patent from the Mexican Government, retains an interest in the property. The sale was arranged by Gen. R. H. Rollins of Los Angeles.

MEXICO.

THE PROMONTORIO GROUP.—Nogales Advertiser, Jan. 20: The Promontorio group of 68 mines, including the famous Tumacacori mine owned by Mr. L. Ephraim of Nogales, is steadily producing and shipping ore. Mr. Ephraim has 65 men at work, extracting and developing different leads in the group. The mines are all within a radius of about one mile, and the ore runs from \$40 to way up in the hundreds, as the ore is assorted. This variety enables Mr. Ephraim to ship large quantities at any time. If silver is up, he ships the lowest grades; if down, the higher grades are selected. Even should silver value go to 75, Mr. Ephraim could still ship at a profit, having such large quantities of rich ore. The last several cars were sampled at \$210 per ton. The daily expenses are about \$250, the bulk of which is taken out of the well-stocked store at the mines. This store supplies about five hundred persons, and a large profit is realized from this source. About \$2000 of the money paid out at these mines drifts into Nogales. Mr. Ephraim is the heaviest mining tax-payer in Magdalena district, and many consider that he has the finest mining property in the State of Sonora, with possibly two or three exceptions.

SOUTH DAKOTA.

BLACK HILLS NICKEL DEPOSITS.—Black Hills Journal, Jan. 19: In conversation with a Pioneer reporter while in Deadwood, Sam Scott made some interesting statements concerning the nickel and tin deposits at Harney City and about four miles from Hayward. The nickel and tin deposits run parallel, and lie between Battle creek and Iron creek, and the company's

property embraces about 960 acres, on the nickel portion of which only assessment work has been done, although this has been enough to satisfy the owners that the deposit is rich and practically inexhaustible. The discovery of the nickel was made about 18 months ago, but the deposit was not opened in a rich portion and nothing was said of the matter at the time. About three weeks ago further work was begun, in other places along the vein, the result of which was to uncover an immense amount of high-grade nickel ore, on which the assays range from 15 to 110 pounds to the ton. As nickel is worth one dollar a pound at retail and 75 cents a pound wholesale, it will be readily seen that the find is a rich one. And in this connection it might be interesting to add that no nickel is at present being produced in the United States, and the only nickel mines known to be now producing are at Sudbury, Canada, and New Caledonia, and the ore of both places is said to be similar to that found at Harney City. One of the new uses for nickel is in the manufacture of armor plate and artillery guns, hence the market bids fair to be an extensive one.

UTAH.

THE SAN JUAN PLACERS.—A dispatch from Washington dated Jan. 25th says: Secretary Noble transmitted to-day, in response to a resolution of the House, his report concerning the executive order of Nov. 19th, by which that part of Utah west of the 110th meridian is restored to the public domain, together with all correspondence on the subject. The documents show that this land was thrown open to settlement for the purpose of allowing the people of the United States an opportunity of exploring the placer fields in search of gold and other valuable minerals. All of the facts connected with the restoration were published generally throughout the country at the time the President's proclamation was issued. A telegram was received from Colonel Hunt of the army reporting that no prospectors had intruded or were intruding on the Navajo reservation.

THE GOLD FIELDS.—Cocino (A. T.) Sun, Jan. 15: During the week a number of prospectors have returned from the San Juan placer fields and a number have brought in gold, and there is now on exhibition at Babbitt Bros.' some fine specimens of placer gold, and it is now conceded by the most skeptical that gold exists there in paying quantities and that in the largest sense of the words. A good many thousand dollars in gold have already been taken out, and it is what is known as flake and shot gold. It will, however, cost money, to get water on to the bars and to handle the dirt, but as it pays well, the money will be expended. Sam and Mat Black and Martin McCarty have returned; the latter is an old California prospector, and they located on the lower San Juan 20 miles above the mouth. Mac panned out three pans of dirt taken at the top and obtained about 90 cents in gold, and he says that the estimate placed on the placer ground is from five cents per pan to as many dollars. The party ran out of grub, and as soon as they rest up they will return and go to work again. There are three camps in the lower river, and all the valuable ground has been taken up, but back from the river and in the side gulches there is plenty of ground which is just as rich as that along the river. The Arizona & Utah Development Company are finishing up the road to their camp and will put in machinery and commence work as soon as the weather gets warmer. Ice is now running in the river and men cannot work in the water. Hugh Campbell and others have a number of claims below the A. & U. some 20 miles, and they have named the district the Golden Reef. They are putting in sluice-boxes and doing other preparatory work. Parties are going from here nearly every day and hundreds are going from Colorado, and parties who were sent out from Denver to make tests of the placers report that one test returned \$19.60 to the cubic yard of dirt, and another \$12.40. The Navajo Indians do not like the goldseekers to cross the reservation, and it is feared that there will be trouble with them. They cannot understand how a strip of land which they have always claimed can be taken away from them without their knowledge, and the crossing of the reservation of armed men makes them indignant, and it causes a feeling of resentment among them, and they may make it interesting for the white men. However, it is all the more interesting for the searchers for gold, for they think there is just as good chance of their losing their scalps as there is of finding gold.

WASHINGTON.

A NEW EL DORADO.—Spokane Chronicle, Jan. 20: John Blackburn, a prospector, called at the Chronicle office to-day and related a story of ore discoveries in the vicinity of Davenport, Lincoln county, which, if true, promises to equal, if not eclipse, the most sensational tales ever circulated about the late discoveries in the Slovan country. Blackburn is rather an intelligent-looking fellow, and tells his story with an air of seriousness which gives it weight. He carries a bag full of samples with him to demonstrate the truthfulness of his report. The Egypt district is the name of the newly-discovered El Dorado, and is situated about 60 miles north of this city on the Spokane river. Greenville Blake and Clarence McCullough are the names of his fellow-prospectors. Blackburn claims that the vicinity of Egypt is fairly studded with ridges of ore cropping out on the surface and bearing evidence of remarkable richness in mineral wealth. He was led to investigate the Egypt district from the report of an old-time prospector who had once struck it rich there, but had lost track of his find. Blackburn and his friends have located ten claims in the vicinity. The ore consists chiefly of galena, with copper and bromides of silver in abundance. Blackburn expects a big boom in his newly-discovered mining camp in the spring.

Market Reports.

Financial and Commercial Review.

SAN FRANCISCO, Jan. 26, 1893.

Gold Coin for New York.

A contemporary says that \$29,287,250 in gold coin was sent from this city to New York in the mails in 1892, against \$12,458,440 in 1891 and \$929,000 in 1890. It should be explained that of the large shipment last year \$20,000,000 was sent from the Sub Treasury, and consisted entirely of Government coin, the accumulation of years from the collection for duties on imports at this port, and that this large sum was conveyed across the continent by special train under a special guard of United States soldiers. It was thus altogether out of the usual order of remittance, and in no way represented a mercantile business. The same thing happened on a small scale in 1895, when gold coin shipments hence through the mails amounted to \$21,605,750.

Consumption of Tin in the United States.

During the last decade the consumption of tin in this country has nearly doubled, which is best proven by the yearly importations since 1882. Reducing the weight into round numbers of tons of 2,240 lbs, we find that according to the official returns from the Bureau of Statistics in Washington the total importations of tin in bars, blocks or pigs, "grain or granulated," have been as follows for each year, ending June 30th:

1882.	1883.	1884.	1885.	1886.
9,800	11,910	11,600	10,700	12,500 tons.
1887.	1888.	1889.	1890.	1891.
13,200	14,200	15,100	15,600	17,800 tons.

There is no official record of stocks, but taking those of New York, as the principal port of importations as a basis, viz:

1881.	1882.	1883.	1884.	1885.	1886.	
2,000	1,500	1,000	700	1,400	1,300	tons.
1887.	1888.	1889.	1890.	1891.		
300	1,600	900	1,600	1,700		tons.

The yearly consumption has been:

1882.	1883.	1884.	1885.	1886.
10,300	12,400	11,900	10,000	12,600 tons.
1887.	1888.	1889.	1890.	1891.
14,200	12,900	15,800	14,900	17,700 tons.

The consumption for the calendar year 1892 we figure as follows:

Stocks January 1, 1892.	2,000 tons
Importations for 11 months ending Nov. 3, 1892, as per official returns, reduced into round numbers or tons of 2,240 pounds.	19,500 tons
Importations during the month of December, 1892.	1,100 tons
Total.	22,600 tons
Stock on January 1, 1893.	3,500 tons

Consumption in 1892. 19,100 tons

American Copper Product for 1892.

The *Engineering and Mining Journal* of January 14th gives the copper product of the United States for 1892 as follows:

Lake Superior mines, lbs.	107,200,000
Arizona.	38,000,000
Montana.	164,300,000
All other States.	15,680,000
From imported ores.	10,200,000

Total. 335,380,000

The product in Montana was 51,000,000 pounds larger than in 1891. The Anaconda mine of Montana produced 63,000,000 pounds in the first six months of the year. At the beginning of 1892 there was a stock of 33,929 long tons. The amount exported in 1892 was 40,195 long tons, the amount consumed 118,472 long tons, leaving a stock of 25,000 long tons at the close of 1892.

THE METAL MARKETS.—There are no changes worthy of note in the local metal markets. Eastern advices are that the demand for pig iron is improving and prices are firmer. Sales are not hard to make at inside quoted rates, but buyers are still on the defensive and not disposed to buy in advance of requirements, while on the other hand sellers are not offering concessions unless under special circumstances. For steel billets the market is heavy and depressed.

The Mining Share Market.

The mining share market has been a little better this week than last, but not very much. Matters are in an unsatisfactory condition on the Comstock, and, as will appear by an article in another column, a number of prominent men on the lode are discussing the situation with a view to certain reforms in improvements, mainly in the direction of reducing railroad freight, cost of water and cost of milling. These things should have been considered long ago, before affairs got to their present bad state.

Mr. Fox and the other stockholders of the Hale & Norcross Co., who got judgment against Alonzo Hayward, W. S. Hobart and others for \$1,011,835, have not yet got their money. After the judgment had been rendered and a receiver appointed to take charge of the property of the corporation, all of the defendants, with the exception of the estate of W. S. Hobart, perfected an appeal to the Supreme Court from the findings and decree of Judge Hebbard, holding the corporation and Hayward and Hobart jointly and severally liable for the judgment. Under the law, the defendants were required to put up a bond in double the amount of the judgment, which meant that they should justify in the enormous sum of \$2,022,000. On July 6th, just about a month after Judge Hebbard's decision, the Western Surety and Guarantee Company filed articles of incorporation under the laws of the State, with a capital of \$100,000, for the purpose of making, guaranteeing or becoming a surety upon bonds or undertakings required or authorized by law. The capital stock of the company was divided into 10,000 shares of \$10 each, which was fully subscribed by C. D. Lane, \$20,000; Isaac L. Regua, J. P. Jackson, W. E. Dean, G. B. Bowers and D. L. Bliss, each \$10,000; W. J. Dingee, \$15,000, and Ramon E. Wilson, \$5,000.

This company, which is supposed to have been organized to furnish the bond in the Hale & Norcross appeal case, had a small liability for such a big bond. The attorney for the receiver, J. J. Groom, in November last made a motion in the lower court to proceed upon the judgment as though no sufficient bond had been given. The defendants met this movement by going to the Supreme Court and filing a petition for a writ of prohibition restraining the lower court from proceeding in the case. The petition was heard on December 5, 1892, and has been sleeping in the court since. The men who got the judgment are anxious for a decision, but it is still delayed.

At the annual meeting of the stockholders of the Del Monte Mining Company, 187 1/2 shares were represented out of 225 1/2, and the following officers were elected for the ensuing year: E. Scott, president; F. A. Berlin, vice-president; and P. C. Hyman, G. W. Grayson and Thomas B. Pheby, directors. J. W. Pew was re-elected secretary, and his financial statement showed an indebtedness of \$20,824.33.

At the annual meeting of the stockholders of the Utah Mining Company 81,885 shares were represented and the following officers elected for the ensuing year: H. B. Havens, president; George R. Wells, vice-president; Herman Zaidig, A. S. Wallberg and E. B. Holmes, directors. A. W. Havens was elected secretary, vice A. H. Fish. The secretary's financial statement showed a credit of \$1781.20.

At the annual meeting of the stockholders of the North Commonwealth Mining Co., 83,656 shares were represented, and the following officers elected for the ensuing year: E. Scott, Pres.; F. A. Berlin, Vice-Pres.; and P. C. Hyman, G. W. Grayson and Thos. B. Pheby, Directors. J. W. Pew was re-elected secretary, and his financial statement showed a credit of \$1713.34.

It is rumored, says the *Reno Gazette*, that all the mills on the Carson river, with one possible exception, will close down in a few days.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

HOISTING AND CONVEYING MACHINERY.—Frank C. Beach, S. F., assignor of one-half to Louis Rosenfeld, N. Y. No. 489,785. Dated Jan. 10, 1893. The invention relates to that class of mechanism designed for hoisting material from a given point, conveying it thence to another point and there lowering it. The object of the invention is to provide simple and effective means capable of easy and accurate operation, for hoisting coal and other material from given stations, conveying it rapidly to another station, and there lowering and deliv-

ering it gently, whereby breakage is avoided. The invention consists in the novel construction, arrangement and combination of the traveling trolley and the means for operating it and hoisting and lowering the bucket or tub to and from said trolley.

FILTER.—Joseph Kraker, S. F. No. 489,747. Dated Jan. 10, 1893. This invention relates to improvements in filters, and consists in the arrangement of a body of filtering material within an outer enclosing case, with pipes and cocks so arranged that the flow of water through the filter may be reversed at pleasure, both for the purpose of cleaning the filtering surfaces first exposed to the inflowing water and also to filter in the opposite direction when deemed desirable. In connection with these various flow-cocks is another, through which the water may be drawn directly and without filtering. In connection with the filtering devices is a reservoir chamber to receive and store filtered water, and a float-controlled valve is fixed to operate between the filter and the reservoir.

GANG-PLOW.—A. F. McMillan and Thos. Gormley, Benicia. No. 490,210. Dated Jan. 17, 1893. The general object of this invention is to simplify and cheapen the construction of gang-plows, at the same time making them strong, durable, and easily adjustable. The patent covers certain novel features of construction.

AUTOMATIC RELEASING DEVICE.—Hans P. Nielsen, Alameda. No. 490,211. Dated Jan. 17, 1893. The object of this invention is to provide a releasing device simple in construction and operation which can be applied to the releasing of hitched animals, such as horses in fire-houses and livery stables, or to spring-controlled doors or other structures which may be required to be automatically and quickly released. The device is one of that class in which a swinging bar is controlled by a catch operated by the armature of an electro-magnet.

HYDRAULIC-MINING APPARATUS.—Newton C. Miller, French Corral, Nevada Co. No. 489,751. Dated Jan. 10, 1893. Various devices have been used in the attempt to raise gravel and other gold-bearing earth from points where it may be deposited to higher elevations, by the use of a jet of water under pressure, the operation being performed by introducing the jet nozzle into a closed sluice or pipe, so that the velocity of the water will carry up the dirt or gravel which is deposited so as to be acted upon by the stream. The great difficulty encountered in this apparatus has been the clogging up of the discharge-pipe by reason of so great an amount of

heavy material accumulating in it that the momentum of the jet is checked that it will not operate. This invention is designed to overcome this difficulty by introducing, along with the jet of water, a current of air which prevents the choking of the material within the pipe. It also consists in the novel arrangement and construction of the parts of the apparatus. The inventor states that it is especially useful in cases where the gravel or earth is brought in sluices to points so much below the surface of the bedrock that further work cannot be done without first raising it sufficiently to allow another sluice to be put in.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and con-
struction of Ditches, Flumes, Dams, Pipes, Flow of Water
on Heavy Grades, methods of mining shallow and deep
placers, history and development of mines, records of
gold washing, mechanical appliances, such as nozzles,
hurdy-gurdys, rockers, undercurrents, etc.; also describes
methods of blasting; tunnels and sluices; tailings and
dump; duty of miners' lach, etc. A very practical work
for goldminers and users of water. Price, \$5, post-paid.
For Sale by Dewey Publishing Co., 220 Market St., San
Francisco, Cal.

Lidgerwood Improved Hoisting Engines for Mines.

The latest improvements made by the Lidgerwood Manufacturing Company, 96 Liberty street, New York, are embodied in their new single and double drum mining engines.

They are of the well-known form of friction drum engine of the Lidgerwood type, having two separate engines connected to the crank shaft, with cranks set at an angle of 90 degrees. On this crank shaft there is a small pinion which meshes with a large gear wheel, the proportions being from five to one to six to one. This large gear wheel is keyed fast to the drum shaft. On the side of this gear wheel is bolted wooden segments in the form of a double V. The drum is arranged to be loose upon the shaft or to be thrown into friction when it is to take the motion of the gear. It is unnecessary to describe the method of throwing in this friction. It is of a well-known type which has been used for many years, the only improvement being one of proportion. The drum has a differential brake lined with blocks of wood fastened to the band by means of leg screws. The engine has reversible motion, and the lever for operating the links, as well as the lever for operating the brake and the friction, are all brought together in a central position. This arrangement of levers is considered a very great improvement, and has been adopted on all of the Lidgerwood Company's mining engines.

This improved style of engine, it is claimed, unites all the good qualities of the reversible engine, as well as the friction drum engine, and therefore may be used for all work requiring either of these engines. In a single shaft, all the hoisting of ore may be done by the engine in the usual way, and the empty car or bucket lowered by means of the brake, while for hoisting and lowering the men the drum may be thrown into gear and the engine used as a reversible engine, handling the load entirely by steam.

It being a reversible engine, the links may be hooked up after the load is started, cutting off steam at any point of the stroke desired, thus doing most of the work by its

expansion in the cylinders, while by lowering by means of the friction drum end brake the engine does not run and therefore uses no steam.

A valuable feature of this engine is, that while it is designed mainly for single shaft work, it can also be used on a double shaft by simply throwing the friction into gear permanently and using it as a reversible link-motion engine, hoisting the cage and load in one shaft, and at the same time lowering the empty cage in the other shaft.

LIDGERWOOD IMPROVED DOUBLE-DRUM HOISTING ENGINE FOR MINES.

The description of the double drum engine is the same as that of the single drum, the point of difference being that two drums are used instead of one, both absolutely independent of the other; hence, in operation, the same work can be done as though two of the single drum engines were used. These drums may be thrown into and out of gear while the drums are in motion, either separately or together, or one may be lowering while the other is hoisting, or both drums may be thrown into gear and the engine used as a regular reversible engine.

The Lehigh Zinc & Iron Company, we are informed, has been using an engine similar to the double drum engine shown, near Franklin, in the celebrated Franklin Furnace zinc mines. The size of the cylinder is 14x18; the drums are 66 inches diameter and 66 inches face, the whole engine weighing about 50,000 pounds.

THE Rothschild syndicate has borrowed \$10,000,000 in gold in the United States for the use of Austria to aid in her currency reform.

The Sewerage Commission Abolished.

The San Francisco Sewerage Commission, recently appointed, has been summarily abolished by the new Board of Supervisors. The members were Col. Geo. H. Mendell, Prof. George Davidson and Irving M. Scott, with Messrs. Manson and Grunsky as engineers. Since last June, the time of their appointment, many miles of surveys have been made, several sewer systems have

been established and numerous street grade lines have been defined. It is generally understood that the abolition of the Commission was brought about because its existence kept certain fees and percentages out of the pockets of the city and county surveyor. So again we have "politics" to the front in the matter of sewers, and San Francisco must continue without any comprehensive system. This is but a repetition of all public work in this city. For years the necessity of a complete general sewersystem has been recognized, and when this commission of eminent engineers was appointed it was thought that at last something would be done in the proper way. But when about fairly at

work, the gentlemen were displaced without notice and without courtesy of any kind being shown them, in order that officials might obtain certain fees. The members of the commission did not seek the office, and were, perhaps, rather glad to be relieved of the responsibilities, but the action of the supervisors is none the less discourteous. It is true that the supervisors resolved that the work of the commission be continued under the supervision of Engineer Marsden Manson and such assistants as may be required, under the control of the Committee on Streets and the city and county surveyor. Mr. Manson's salary was reduced from \$400 to \$250 per month. His duties are not defined and he is under the control of a committee and a city official. Mr. Manson said that he did not desire to accept the work under the resolution as passed. The order was too indefinite. It divided the responsibility and the duties, and such division in the past has been the cause of a great deal of defective sewer work in this city. It is decidedly unfortunate, in our opinion, that the commission was not continued.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Lidgerwood Improved Double-Drum Hoisting Engine for Mines, 65. Part of Sacramento County's Exhibit at the Northern Fair, San Francisco, 70.
 EDITORIALS.—Lidgerwood Improved Hoisting Engine for Mines; The Sewerage Commission Abolished, 65. Comment; The State Mining Bureau Should be Maintained, 66.
 CORRESPONDENCE.—A Suggestion About the Cyanide Process, 68.
 MISCELLANEOUS.—Foundry Notes; Coast Industrial Notes, 67. Mining with Artesian Well Water; Mining Bell Signals; Iron From Sand; A Proposed State Debris Commission, 68. Mining for Bismuth; Hartley's Meadow Lake Process; The Coast Supply of Timber; Specifications for Road Contracts, 69. The San Juan Placer Region; The Sacramento Exhibit; Weather for February, 70.
 MECHANICAL PROGRESS.—Large Steam Boilers; Steamship Shafts; Gas for Cooking; Fast Torpedo Boats, 71.
 SCIENTIFIC PROGRESS.—The Medical Use of Compressed Gases; Natural Selection at Fault; The Preparation of Chrome, 71.
 ELECTRICITY.—Lighting Factories by Electricity; Slippery Tracks; Distribution of Electric Power, 72.
 USEFUL INFORMATION.—Abolishing London Fogs; A Chance for Inventors; Manganese in Russia; Substitute for Lead Glass; One Virtue of Glimmer; Miscellaneous, 74.
 MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings, Assemblies, Dividends, Etc., 79.
 MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific States and Territories, 77-79.

Comment.

The manufacture of common powder and high explosives is a very important industry in this State and large capital is invested in the plants. Immense amounts of powder are made and sold throughout the coast. It is also shipped away to Mexico and other foreign countries. Great quantities are used in mining, railroad building, quarrying, etc., and this branch of manufacture has become among the most important we have here. It will be well, therefore, for the Legislature to look carefully into the subject before attempting to pass such laws as will so restrict the business as to drive it away. It is all very well to place some restrictions on powder manufacture with relation to the location of works near cities and towns. There can be no objection to that. A bill now pending, however, in the Legislature prohibits the manufacture of powder within four miles of any city, town or village, railroad or public road. The factories must ship their products by road or railroad and by sea and must have ordinary facilities for carrying on business. There is no necessity for driving them out of business on the plea of regulating the location of the works. We have all too few manufactures in and near this city, as it is, and should encourage instead of discouraging them. There can be no objection to reasonable restriction in the location of powder works, but the Legislature should exercise some judgment in the matter. There are no places on the bay shore where works could be built and yet be five miles from a railroad or public road.

Senator T. L. Ford, of Sierra Co., has introduced in the legislature a bill, entitled an Act to amend the civil code by adding thereto two sections, to be known as sections 1424 and 1425, being title IX, part IV, Division 11 of the code, concerning the manner of conducting the business of hydraulic mining. The proposed sections are as follows:

Sec. 1424: The business of hydraulic mining may be carried on within the State of California wherever and whenever the same can be carried on without material injury to the navigable streams, or the lands adjacent thereto.

Sec. 1425: Hydraulic mining, within the meaning of this title, is mining by means of the application of water, under pressure through a nozzle against a natural bank.

The first of these sections is in line with recent decisions of the U. S. Circuit Courts, which permits this kind of mining to go on where no damage results. If damage can be proved work will have to stop. The second section is a very terse and well-worded definition of hydraulic mining. There should be no objection whatever to the passage of this bill since no change is made in existing conditions such as would be detrimental to opposing interests.

At a meeting in London the directors of the San Jacinto estate (Temescal tin mine) decided to wind up the con-

cern, and let it pass into the hands of the holder of the first debenture bonds. This is the end of the English tin-mining company's operations in this State. Last week the sheriff sold at auction a quantity of the movable property of the company to satisfy the accounts of parties to whom the company was indebted when the mine was closed down some months ago. The closing of the mine was a serious loss to the merchants of the section, as well as to labor, as the company, during the time the mine was in operation, disbursed many thousands of dollars monthly. Of course those who took the first bonds now own the property and may eventually utilize it, but, for the present at least, operations in the mine have ceased. The thousands of people in England who invested in this mine have lost their money entirely, the company having decided to "wind up." Too much was paid for it in the first instance, and this may be really a job on the part of the insiders to get it at a reasonable figure. But this is small comfort to those who invested on the representation of the promoters. The mine was never much more than a prospect, and there was never much money spent directly upon it to prove its worth. Thousands were spent on irrigation and agricultural projects on the estate, but the mine itself has not yet been properly tested. Some tons of tin were produced, but no systematic efforts were made to "go to the deep" for more extended deposits. This may have been all part of a plan, as some suspect, or it may have been just mere stupidity. At all events, the bondholders get the estate, mine and all. Part of the land, if sold, would return all the bondholders ever paid, and they would have the mine and works and some thousands of acres of land left. It is very unfortunate for this tin mine that it should have been made, in some sort, a political issue. The failure now will emphasize what was said of tin-mining during the recent campaign. At the same time, as we have said, the mine itself was never given a fair chance. There may be extensive deposits of good tin ore, for all the miners know. With the abundant capital at hand, deep and systematic explorations should have been made, instead of rushing things on the surface to produce a few tons of marketable tin. This failure will be set down against California mines, and adds another to the list of those which discourage the investment of British capital in this State.

No definite action has been taken by Congress with reference to the Caminetti hydraulic-mining bill. Judge Niles Searles has arrived in Washington on behalf of the California Miners' Association, and thinks the bill will probably pass the Senate in a few days. No attempt will be made to further amend the bill by the Senate committee, but it will be amended in conference. The idea of the miners is to modify the penalty clause so it will not be enforced until the Government Commission is organized and ready to issue licenses to mine. As the bill now stands, mining would have to stop where being carried on legally, and it may be a year before the Commission is ready to grant licenses. Of course, the delay jeopardizes the passage of the bill, a fact very well understood by the miners; but most of them prefer no new law at all to one drawn as this is at present. The San Francisco Chamber of Commerce has indorsed the action of the Miners' Association in asking for a modification of the Berry amendment. The following resolution explains the action of the Chamber:

January 25, 1893.

The Board of Trustees of the Chamber of Commerce of San Francisco in session this day.

Resolved, That we concur in and fully indorse the efforts of the Executive Committee of the California Miners' Association in their efforts to secure the passage by the Congress of the United States of the measure known as the "Caminetti Mining Bill," with amendments and penalty clause, as now pending before the Senate, excepting that the compulsory clause of section nine of said bill and the penalty clause recently added thereto shall not become operative until the commission provided for in said bill shall have matured their plans sufficiently to specify those hydraulic mines which are now prepared or in a position to operate without damage to navigable streams, and we urge our Senators and Representatives to so amend the said bill that mining interests already in operation shall not be forced to stop, but should continue to operate under existing laws pending the investigation.

A true copy. Attest: THOS. J. HAYNES, Secretary.

[SEAL]

The foundryman and mechanics of this city are interested in the Hawaiian annexation question to a certain extent, since, should these islands come under the American flag there would be a large extension of our commerce and trade in that direction. We have already profited to a considerable extent in the enterprises in Hawaii, since boilers, water-pipes, sugar machinery, engines, etc., needed there are mainly made in this city. With the protection of the American flag and the resultant immediate enlargement of the sugar interests of the islands, there would come extensive demands on our local foundrymen and manufacturers cheerful to contemplate, more especially in view of the prevailing dullness. Our local ship-building interests also would feel the effects; and, if the islands were annexed, this country would have to maintain more men-of-

war on this coast at all times, all of which would be good for local business. Whatever the opinion of the rest of the country may be, California would be very glad to see the stars and stripes waving over Hawaii.

In another column of the PRESS will be found the full text of Senator Ford's bill now pending in the Legislature and providing for a State Debris Commission. The sum of \$250,000 is to be appropriated for the purpose of building dams to keep back the debris in the rivers, but this is only to be available in case the Government appropriates a like sum; otherwise no expenditure is to be made. Senator Ford's idea is to be prepared for the passage of the Caminetti bill, which looks to the appointment of a State Debris Board to consult with that of the U. S. Government. Unless the Government takes some action in the premises, the State takes none. Senator Ford's bill will doubtless provoke some opposition from valley men, as does any measure connected with mining debris; but as it is intended to keep back debris now in the rivers they ought to support the measure instead of opposing it. It is intended to appoint only one Commissioner so as to lighten expense, but he should be a mining engineer of first-class standing, competent to advise with the army engineers who will compose the U. S. Commission.

California miners should remember that the State law requires them to record with the county recorder of the county where their claim is situated an affidavit that they have performed the annual assessment work required by the U. S. laws. The affidavit must describe the labor performed and improvements made, and the value thereof, which affidavit is prima facie evidence of the fact therein stated. The law states that failure to make this record within 30 days leaves the claim open to relocation. Whether such a provision can be enforced is doubtful, since the claim is taken from Government land, and the assessment work is a Government requirement, with which the State has nothing to do. However that may be, it will be well for miners to record the work done up to Jan. 1st. If they have not yet recorded the work, they will be outside the 30-day time limit, but should do it even now to save trouble. The idea is a good one to have this work recorded, and the U. S. laws should have made such provision. As matters stand now, there is no official way of finding out whether the year's work was ever done or not, and this stands frequently as a bar to titles of claims and prevents their sale.

ARGUS GOLD CAMP.—J. B. Skewes, formerly a mining superintendent at Bodie, has been in the city during the week purchasing machinery to take down to the new Argus camp. He obtained a Kendell one-stamp mill, gasoline engine, assay outfit, etc. The mines are 80 miles from Mohave and about 60 miles from the line of the Carson and Colorado railroad. The nearest mining settlement is Darwin, in Inyo Co. In the new camp water is scarce, or larger machinery would have been purchased. That which has been procured will be in operation in about three weeks. Argus is a gold camp in the Argus mountains, with good grade ore running from \$20 to \$50 per ton.

GEORGE SPAULDING, the well-known printer, who died in this city last week, was employed as foreman on the MINING AND SCIENTIFIC PRESS during its earlier history. In 1869 he and Harrison Barto bought out the MINING AND SCIENTIFIC PRESS job-printing department, which they developed into an extensive business now conducted by the corporation of which Mr. Spaulding was the head. Mr. Spaulding was a director of the Mechanics' Institute for 14 years and very prominent in Masonic fraternities. He was a very popular man, earnest in everything he undertook, thoroughly honest and upright, and one who will be greatly missed by his friends and associates.

THE MINING BUREAU REPORT.—Assemblyman Shanahan has introduced a bill calling for an appropriation of \$10,000 for the printing and issuance of the Eleventh Report of the State Mineralogist. The report referred to is that already prepared, but which the board of examiners referred to the legislature as too voluminous. They made no criticism on the contents, but thought more careful editing would have greatly reduced its bulk without injuring its utility.

A CORPS of United States Coast Survey officers is at Santa Monica and will immediately proceed to survey the harbor and vicinity, which is made necessary by reason of the Southern Pacific company having built a wharf here.

THERE is some talk of moving the Anaconda smelter to Great Falls, Mont., where there is plenty of water and power.

SALT LAKE CITY is to have a silver convention or congress on June 5th, 6th and 7th of this year.

The State Mining Bureau Should be Maintained.

Assemblyman Julius Kahn of this city wants to abolish half a dozen State commissions and consolidate several others, and he has an earnest supporter in Senator Langford of San Joaquin—one of the few counties of the State where there are no mining interests. Naturally both these men want to abolish the State Mining Bureau, probably knowing little or nothing about it and having no interest in its work or purposes. In speaking of the State commissions and his ideas of abolishing them, Senator Langford the other day said: "The most vicious of all these commissions, however, is the State Mining Bureau. Why, its printing bill alone is over \$10,000 every two years." The criticism of a purely agricultural county man on a mining bureau can scarcely be worth much or carry any weight. In the view of such a man the expenditure of \$10,000 for printing a report on mining work would seem "vicious." The idea of excessive cost of printing reports is not original with him, however. The Governor himself, in his official message to the legislature, called attention to the total lack of editorial work in the Mining Bureau report, and said a more careful preparation of the manuscript would save a great deal of money. He had some suggestions also with reference to the improvement of the method of conducting the bureau. He did not, however, suggest the abolition of the institution. So far from doing this he wanted to see the powers of the trustees enlarged, with a view of securing better results.

Neither Assemblyman Kahn nor Senator Langford have any reputation as mining men that we ever heard of. If some man from a mining county, with practical experience on the subject, will formulate a bill embodying Governor Markham's expressed ideas concerning the bureau there will be beneficial results to the institution and the mining industry. The mining men in the legislature, however, should resent the interference of men ignorant of their industry in anything which affects it. The Mining Bureau can very easily be made more efficient than it has been, but there is no necessity of abolishing it. The Bureau is the only institution maintained by the State for the benefit of the great industry which built it up. It would be better to improve than wipe it out of existence.

The trustees who form this commission get no salaries and have no patronage. A very extensive museum is maintained for the public; and an annual report is published giving the results of the work accomplished by the State Mineralogist and his assistants in the field. As long as the miners want this Bureau they should have it, and it would be but graceful for others to leave any suggestions concerning it to the class for whom it is intended.

Foundry Notes.

A. P. BRAYTON, President of the Pelton Water Wheel Co., has returned from a business visit to New York.

WORK is progressing rapidly on the new buildings for the Fulton Iron Works at Harbor View, a large force of men being engaged. The foundry building is completed, with the exception of the corrugated iron roof. The core ovens and brass furnaces are completed, and the smokestack for the main furnaces is up. The machine-shop building is well under way and will be completed within two weeks. It will not be more than a month before the whole new plant will be in order. The machinery, some of which is on the spot, will be of the latest patterns and designs.

It is probable that in the construction of the new ferry depot and the new postoffice the Pacific Rolling Mills will come in for a good share of work. The girders, beams, etc., which will be necessary, must be large and heavy and as the Rolling Mills are equipped to turn out just such work, it will naturally come to them. Mr. Edbrooke, the supervisory architect of the Treasury, in company with the inspector of public buildings, visited the Rolling Mills and Union Iron Works last week to get an idea of the kind of work turned out and the capacity of the plant for heavy beams.

THE Skeena river cold-storage plant, for fish, etc., is very successful, and the Vulcan Iron Works of this city, which built it, among others, will soon have more orders for similar ones. The Skeena works are particularly adapted for fish, and many carloads of fish have been shipped away since the plant was established. Mr. C. J. Koefed went up from this city and superintended the erection of the plant, on behalf of the Vulcan Works. A series of rooms are arranged with shelves upon which the fresh-caught fish are placed, and by means of a number of pipes containing ammonia in a gaseous form the temperature is lowered from 12 to 20 degrees below freezing. In a few hours the fish are frozen solid and can be handled like so much cordwood. The machinery necessary to accomplish this is of a very simple nature, consisting essentially of an engine and the ammonia condenser with the series of pipes. The air is forced out of the pipes and the vapor from the condenser takes its place, and by absorption produces a temperature which keeps the pipes continually covered with a thick coat of frost. Among the advantages of the system are, the fact that there need be no longer an idle season, for as soon as the salmon run is over other fish can be handled to advantage. Vessels need not wait for a cargo of fish, which loses much in quality while being collected, as now the frozen fish can be loaded on it in a few hours from the store-room and reach the market with all its original flavor and freshness preserved. A large quantity can be collected and held for transportation, when opportunity is afforded, and in many other ways the new system is bound to be successful. Arrangements have been made to secure transportation suitable to the growth of business, and this new branch of the fisheries trade bids fair to become a very important one.

Coast Industrial Notes.

A LARGE plant is to be established at Kalama, Wash., for the purpose of freezing sturgeon. Its capacity will be twenty-four tons of fish every twenty-four hours.

THE steamer Emily took away Wednesday a 43-ton locomotive for the Coos Bay and Roseburg Railroad, to run on the 22 miles of road already in operation between Marshfield and Coquille City.

AN ice factory, to be built by Eastern capitalists, is the next manufacturing industry to be established at Petaluma. It will probably be established and in running order for the coming summer.

The big bridge which the Southern Pacific company has been building over an arroyo to the north of their present track and a few rods from the bridge which crosses the Colorado river near Salton is completed. This bridge and track do away with all possibilities of a washout such as occurred in February two years ago.

THE directors of the Linda Vista irrigation district, San Diego county, this week opened bids for the purchase of \$840,000 worth of bonds. There was only one. It was from Wade & Cooper, representing one of the largest syndicates of bond-buyers in the United States, and was an offer of 90 cents on the dollar. It was accepted.

The first silk woven into goods in San Diego county has just been completed by Mrs. Lou Perin of Coronado, to be used for the World's Fair banner. She is now at work weaving a hundred yards of silk from cocoons raised at San Diego, which will be made into dresses as soon as completed.

THE California Oil Works have purchased a lot on University avenue, Berkeley, adjoining Neihaus' planing mill, and are tearing away the building thereon preparatory to the erection of a large brick building. It is rumored that the manufacture of coconut oil will be carried on. Some of the machinery is already on the ground.

ONE of the largest cement ditch contracts ever undertaken in San Bernardino Co. is now rapidly nearing completion. The Gage canal, which furnishes the water supply for the new settlements of Riverside, will be cemented for a distance of six miles. Gray Brothers' of Los Angeles have the contract, and a large force of men and teams has been employed in the work for many weeks past.

THE Monterey has been towed to Mare Island from the Union Iron Works by two tugs. Ammunition and supplies were put aboard her and she was formally received by the Government. Naval officers concur in the belief, however, that she will be kept here to defend San Francisco in the event of trouble with England or any other foreign power.

THE contract for the construction of the South Gila canal has just been let to Irland & Vickry of Los Angeles. The work when completed will cost \$2,000,000. The main canal will be seventy miles long with an average flow of six feet of water and will cover 161,000 acres of land. This is high mesa land on the south side of the Gila, in Yuma county, A. T., and is especially adapted for early fruit raising.

ASSEMBLYMAN CURTIS has introduced a bill in the legislature making it unlawful for any person to set up as an architect who has not served a five-year apprenticeship with a registered architect, and all architects now doing business must within 90 days register with the Controller of State, who shall charge a fee of \$10 for issuing such certificate. The bill was prepared by the San Francisco Chapter of the American Institute of Architects.

In a Los Angeles case the Supreme Court has decided that a laborer or a materialman cannot assign his mere right to assert and claim a mechanic's lien by complying with statutory provisions and clothe the assignee with the power to create the lien for himself. The Supreme Court says the legislature may not have thought that it would have been advantageous to a laborer to allow him to fritter away his wages at a ruinous discount to money-lenders.

THE recently formed irrigation district known as the Riverside Heights district, which comprises a quantity of land east of Riverside, has just begun the work of water development. The land in the district has been bonded for \$30 an acre to prosecute the work. The district will run a tunnel into the Box Springs range of mountains lying adjacent and east of the district lands, from which a supply of water will be drawn. The prospect for an abundant supply is good.

THE McClellan Ore Concentrator Company is establishing works at 126 Main street, this city, for the purpose of manufacturing the McClellan Concentrator. The claims for this machine are, that it is simple in construction and operation, very durable and a close saver of concentrates, besides being built at less cost and requiring less power than other machines for the purpose. Messrs. McClellan & Son are experienced miners and millmen, and no doubt more will be heard from this concentrator.

THE San Francisco and San Mateo railway will shortly commence work on its park extension from Eighteenth and Guerrero streets up the former westerly across Corbett road to Ashbury street, and thence by Frederick and Waller streets to Stanyan street, one block south of the Haight-street entrance. The single track now laid on Eighteenth street is to be replaced by a double track, and a short feeder is also to be built at the same time from Ashbury street and Clarendon avenue on the latter to Stanyan street, with the terminus facing "Sutro's farm," lying adjacent to the Clarendon Heights district.

A PRIVATE letter received from St. Paul, Kodiak Island, Alaska, by the schooner Undaunted, states that it was the salthouse and outbuildings of the Russian-American Packing Company's cannery, at Afognak, that were destroyed by the terrific rainstorm of November 24th and not the main buildings, as previously reported. The superintendent of the cannery, Edward Jones, who was killed by the collapse of the salthouse, was a native of Wales, 40 years of age and single. George Fogel, president of the can-

nery company, said yesterday that the main cannery buildings were well above high-water and strongly built. Their value was between \$20,000 and \$25,000. From what he had been able to learn the damages to the outside cannery structures would not exceed \$5000.

At a meeting of the Trades and Labor Council a committee on the grouping of trades reported that they had classified them as follows: Building trades—carpenters and joiners, painters and decorators, gilders, rattan-workers, pattern-makers and upholsterers; leather trades—Shoemakers' League, harnessmakers, finishers and tanners and curriers; iron trades—ironmolders, horseshoers; American order of Engineers; printing trades—printers and typographical unions; liquor and luxury trades—brewery workmen, barbers, coopers, cigarmakers and cigartuckers; food trades—bakers, bakers and confectioners, and cooks and waiters; water front—sailors and derrick men.

At the Stanford University, Palo Alto, a new brick power-house, 100x75 feet, has been finished, but the machinery will not be transferred to it until the summer vacation. It is designed to contain one 250 horse-power engine and one 125 horsepower and three dynamos. The present power-house will be used only as a boiler-house. The new foundry is built of brick and is 200x40 feet. The floor is made of firmly-packed clay. Twenty-four anvils and twelve forges are being set in place, and space is provided for more when needed. A portion of the building will be occupied by lathes and other machines for iron and steel. Another portion is reserved for use as a general repair shop for the mechanics employed by the university.

MARE ISLAND NAVY YARD mechanics are to build two new boilers for the revenue cutter Corwin. The four new boilers for the Monadnock have been recently tested under the supervision of Chief Engineer Burnap and Foreman Campbell. They stood the test admirably, and will be taken down to the monitor in a short time and placed in position. They are twelve feet two inches in diameter and are made of steel fifteen-sixty-fourths of an inch thick. They are built to carry 160 pounds of steam to the square inch, and the test subjected them to a pressure of 250 pounds. Foreman Campbell and all the boiler-makers under him admit them to be the finest set of boilers ever turned out. The Corwin's boilers will undoubtedly come up to the same degree of excellence.

THERE were in port Tuesday and on the disengaged list 57 vessels, aggregating 105,200 registered tons, as against 78,700 tons on the corresponding date last year. This list included 12 American, 42 British, 2 German and 1 Norwegian. There was not even one American vessel on the wheat-engaged list, all being under the British flag except 1 Italian and 2 German vessels. Iron vessels invariably receive the preference, as shown by the fact of there not being a single wooden one on the engaged list. All of the American vessels on the disengaged list were wooden. The Cape Horn route has provided employment for a good amount of American tonnage, and the merchandise traffic by the same appears to be well sustained. There were three ships on the list for New York, the Charming, Servia and S. P. Hitchcock. The amount of tonnage of all classes headed for this port yesterday from all sources was 263,800 tons, against 233,800 on the same date a year ago.

THE Senate Committee on State Prisons is considering a bill to make an appropriation for establishing a cordage factory at Folsom. Captain Aull's testimony showed that if the proposed cordage plant was put in at Folsom and the product sold at a small margin above cost, a number of free laborers would be thrown out of employment. There are at present 112 white persons engaged in the Tubbs factory. Since early in December no Chinese had been employed. Prior to that period, however, many had been employed. The work formerly performed by them was now being done by girls. Secretary Kellogg, of the Tubbs Cordage Co., said it was not a part of any combine, and that for the past five years about six per cent had been realized on an investment of \$1,000,000. The annual output had averaged 6,000,000 pounds. The capacity of the plant was 12,000,000, and the consumption of this coast 10,000,000 pounds. There was considerable competition from the East. If a factory were established by the State and run by convict labor, the company would have to suspend. Mr. Kellogg admitted that Chinese labor had been employed, but that the Chinese house on the grounds had been torn down and white girls, earning from \$1.25 to \$1.40 a day, were now doing the work formerly performed by the Chinese. In future none but white operators would be employed.

THE following is the copy of a letter received by the Westinghouse Electric Co.'s agent in this city from Mr. G. H. Winslow, superintendent of construction of the San Antonio Light and Power Co.: "Regarding the transmission you will be interested to know that the whole outfit of converters was connected up in Pomona and 10,000 volts delivered to it for a short time without a flaw in anything. As a result the San Antonio Light and Power Co. the next day ordered 19 more converters, so as to be able to also operate San Bernardino at that pressure. Then we used about 8000 volts for about a month on Pomona, the S. B. line not being ready; then we reduced this to about 5000 volts, which allowed us to take half the Pomona converters to San Bernardino and operate that line also at 5000 volts. We now have about 600 lights in Pomona and 200 in San Bernardino, 200 more contracted for New converters will soon all be here, when we will run at 10,000 volts on both lines. The San Antonio people are very much pleased at the success of the plant. Much of the time at the start we ran with hand-governing of water-wheels, but now we have an excellent governor on both generator and exciter, lately designed by the Pelton people. The original plans and specifications for this plant were drawn by Mr. A. W. Decker, E. E., the consulting and supervising engineer of Sierra Madre, Los Angeles county. The line distance to San Bernardino is 30 miles; to Pomona 16 miles. This is the longest-distance transmission in the world."

A Proposed State Debris Commission.

The following is the full text of Senator Ford's bill introduced Jan. 20th, to provide for the appointment, duties and compensation of the Debris Commissioner, and to make an appropriation to be expended under his directions in the discharge of his duties as such commissioner:

The People of the State of California, represented in Senate and Assembly, do enact as follows:

SECTION 1. The Governor of the State of California shall, on or before the first day of January, eighteen hundred and ninety-four, appoint a competent civil engineer, for a period of four years only, to be known as and called the Debris Commissioner.

SEC. 2. Said Commissioner shall, during the time he shall be actually employed in the discharge of his official duties, receive a compensation of three hundred dollars per month, and his necessary traveling expenses, to be allowed by the State Board of Examiners.

SEC. 3. Whenever any Board of Engineers of the United States Government shall have been appointed with power to adopt plans and specifications for the construction of works for the impounding of mining debris, it shall be the duty of said Debris Commissioner to consult and advise with such Board of Engineers of the United States Government, and to examine and pass upon the merits of such works, and said Debris Commissioner shall determine whether or not such works are calculated to and sufficient to protect the navigable waters of the State, and to keep a record of such determinations.

SEC. 4. There is hereby appropriated out of the general fund of the treasury of this State not otherwise appropriated, the sum of two hundred and fifty thousand dollars, no warrant against said sum to be drawn or paid until the United States Government shall have appropriated at least an equal amount, to be used in the construction of works for the restraining and impounding of mining debris in California. Said money to be paid only upon orders only drawn by the Controller, upon the written request of the said Debris Commissioner, and to be drawn for the payment of not more than one-half of the cost of the construction of any such works for restraining and impounding mining debris as shall have been approved by him and duly adopted and recommended by engineers of the United States Government appointed for that purpose.

SEC. 5. The term of office of said Debris Commissioner shall be four years from the date of his appointment. He shall take the same oath of office as is provided by law for other State officers, and before he enters upon the discharge of his duties shall give bond, with sufficient sureties to be approved by the Governor of the State, in the sum of fifty thousand dollars, for the faithful discharge of his duties as such officer.

SEC. 6. The said Debris Commissioner shall have the power to appoint a secretary, at a monthly salary to be fixed by said Commissioner, not exceeding one hundred and twenty-five dollars per month. Said secretary to hold office at the pleasure of the Commissioner. And the State Controller is hereby authorized to draw his warrant monthly in favor of said secretary upon the order of said Debris Commissioner. Provided, however, that no secretary shall be appointed until said Debris Commissioner shall enter upon the actual discharge of his duties.

Mining with Artesian Well Water.

Frederick H. Edwards of Kimbola, West Australia has come from England, where he has been arranging with some capitalists of London for the formation of a large water-scheme to enable the gold deposits in the interior of West Australia to be worked with advantage.

Interviewed by a reporter Mr. Edwards explained how he intended to transform the barren desert into a scene of bustling activity.

"I have known for many years of some rich gold country which it was impossible to work on account of there being no water within 100 miles. Having studied the formation of Australia, I came to the conclusion that there must be water beneath the surface, if it could only be reached. The whole country is shaped on the surface something like a basin, the interior being far below the sea level. Therefore it is obvious to me that the heavy rains and floods of the winter season, which flow from the high coast ranges, must settle somewhere, and the interior is the place that it goes to.

"After several abortive experiments I succeeded in putting in a bore, with the result that a fair flow of brackish water was obtained. Now, with sufficient machinery I am confident that by reaching a greater depth I can get an endless supply of fresh water, and a few of these artesian wells sunk there would work wonders.

"I obtained a grant of all the land I want from the Government and went to England looking for capital, which, on account of the depression in Australia, I was unable to find there. As soon as I get back I shall start work, and hope to have half a dozen artesian wells spouting on the property within six months. Then you will see one of the finest gold fields in Australia opened up, that will probably exceed those which created such rushes some years ago at Ballarat and Bendigo."

THE North American Navigation Company has secured the entire \$100,000 required by the Paoama Railroad Company. It has sent back the contract between the two companies and with it a schedule of freight rates that will have to be ratified by the railroad company. Some minor changes were made in the contract, but they affected only the details and not the main features. It is expected that the steamers for the new company will be ready for service by February 15th. Five steamers will be required in the company's business and already three have been picked out and the company is making arrangements to charter them.

A Suggestion About the Cyanide Process.

REDDING, SHASTA CO., CAL., Jan. 28, 1893.

TO THE EDITOR: I notice in your issue of the 21st a letter from A. B. Paul, who, with his colleague, Mr. Garlick, owns the MacArthur-Forest process for Shasta county.

Everybody around here knows that Mr. Paul has been experimenting on this process for several months past, and everybody knows that he has spent a great deal more money than he has been able to extract out of the ore he has been treating. Now the works are shut down at present and presumably all the gold has been leached out of the tanks so that it would be a very easy matter for Mr. Paul to inform us who wish to adopt this method what are his total results; say how many tons of ore he has treated; what was the assay value of the pulp; what is the total bullion recovered; and what have been the total working costs at the mill.

In Mr. Paul's letter he laments the loss of his assayer for the sake of the "dear people," but if Mr. Garlick was consulted he could tell how much money the process had cost him, and if you add to that what it has cost Mr. Paul the "dear people" would learn something which would enlighten them more about this process than all the letters which have yet been published on the subject. It is possible that Mr. Paul has been experimenting with ore which does not contain sufficient gold to pay, but Mr. Paul has been experimenting with this same ore for years and all the time he felt sure he was losing enormous quantities of gold in the tailings; and all he has been praying for during all these years was a process to extract a fair percentage out of the ore. Now when he has got the process, alas! he discovers that the gold is not in the ore.

I agree with Mr. Paul very heartily when he says that there never was any new system put before the public with so little instruction for a successful outcome, and the wonder is that under such circumstances the process has made the advancement it has. I will ask Mr. Paul to tell us what advancement it has made in Shasta county. Nor do I believe it will ever make any advancement until the owners of the process will undertake to do what was done in South Africa—viz., to erect works at their own expense to responsible parties who will pay for the same when the process has been worked successfully for a reasonable length of time. If we have to pay for patent rights and royalties on a process which cannot be guaranteed to do what is claimed for it I am afraid very few will be induced to go to the expense of erecting the necessary plant and take all the risks of experimenting afterwards.

Now I would suggest to Mr. Paul that he get a list of those mines in Shasta county which by the ordinary process would lose over \$5 per ton in the tailings and make the mineowners an offer to erect a plant and work the same for say six months or until it has paid for itself, then hand over the plant with patent rights and royalties included for a sum equal to what it has cost to build the plant.

Supposing the plant cost \$5000, Mr. Paul's company to recover \$5000 net from the tailings, then hand over the plant for \$5000 cash. If Mr. Paul would do that then the "dear people" would understand that there was some intrinsic merit in the process, as they did in south Africa. Now it is all bosh to say there is a difficulty in getting rock with gold in it, because to my knowledge there are a dozen mines in Shasta county which if the ore was milled and amalgamated in the ordinary way there would be a loss of at least \$7 per ton in the tailings.

Mr. Paul knows these facts as well as I do, and yet he has spent 12 months experimenting with a low-grade rock that will not average \$3 per ton in the pulp at a great loss to himself and colleagues at a cost which if it had been spent as above mentioned he might have had five or six plants at work on \$12 ore within a radius of ten miles of Redding.

It is my opinion, for when we consider the failure Mr. Paul has made in making both ends meet, from whatever the cause may be, the uncertainty attending this process on different ores, and the want of a guarantee given by the patentees who wish to collect royalties on the number of tanks whether the process be successful or not, that the miners of California are wise in not risking their money on such an incomplete process where sulphuretted ores have to be treated; and by waiting a little longer the cyanide process will be so perfected that capitalists will join in building plants and take their profit out of the tailings.

A SHASTA MINER.

Iron From Sand.

The iron sands of New Zealand have once again been brought under public notice, this time by the medium of a former Sheffield metallurgist, Dr. W. T. Spencer, who is now residing at Napier, in our southern Pacific colony. This gentleman has, we understand, says *Iron*, patented a process for treating the ferri-ferous arenaceous deposits by electricity, by which, it is claimed, steel of the finest quality is produced. The iron sand found at Taranaki, New Zealand, and in other countries is, with the exception that it contains another metal, titanium, of the same composition as the magnetic iron ore which is met with in large quantities in Scandinavia, China, Siberia and a few other localities; and like the last-named mineral, it is attracted by the magnet. Alexander Watt says that the sand furnishes excellent steel. The theory of the formation of these iron sands was propounded by the late J. Arthur Phillips. Many crystalline rocks, he reported, contain magnetic and titaniferous iron ore interspersed in small grains and crystals. Such rocks, when disintegrated, give rise to the black sands which are abundantly found in alluvial gold-diggings and elsewhere. Along the littoral of countries in which crystalline and eruptive rocks abound, streaks of black sand washed out by the action of the waves, are frequently met with in sufficient quantity to admit of their being employed as an ore of iron. Among these localities may be

mentioned, in addition to Taranaki, the shores of the Bay of Naples, and many points of the northeast coast of British America, the most important deposits being situated along the north shore of the St. Lawrence, east of the Moisie river. At Moisie, where these sands form a large portion of the beach, after the prevalence of certain winds, belts of nearly pure black sands, which have been concentrated by the action of the waves, are found along the shore. The purer and thicker layers are separated by shovels from the more siliceous portions, and are afterwards further concentrated by washing. When thus freed from the minerals with which they are associated, these black sands consist of nearly equal portions of magnetic and titaniferous iron. Similar iron sands occur at several points along the coast of Labrador, where they are associated with quartz, garnets and feldspar. Mr. Phillips did not find that these iron sands had been successfully employed for the production of cast iron, owing to their finely-divided state; they are only adapted for the direct manufacture of wrought iron and steel.—Boston Journal of Commerce.

Mining Bell Signals.

The following is the full text of the "Mine Bell Signals" act presented by Senator Voorheis before the Senate and which passed that body Jan. 18th, being the first bill to pass the Senate:

SECTION 1. Every person, company, corporation, or individual, operating any mine within the State of California—gold, silver, copper, lead, coal, or any other metal or substance where it is necessary to use signals by means of bell or otherwise, for shafts, inclines, drifts, crosscuts, tunnels and underground workings—shall, after the passage of this bill, adopt, use and put in force the following system or code of mine bell signals, as follows:

- 1 bell, to hoist. (See Rule 2.)
- 1 bell, to stop if in motion.
- 2 bells, to lower. (See Rule 2.)
- 3 bells, man to be hoisted; run slow. (See Rule 2.)
- 4 bells, start pump, if not running, or stop pump if running.
- 1—3 bells, start or stop air compressor.
- 5 bells, send down tools. (See Rule 4.)
- 6 bells, send down timbers. (See Rule 4.)
- 7 bells, accident; move bucket or cage by verbal orders only.
- 1—4 bells, foreman wanted.
- 2—1—1 bells, done hoisting until called.
- 2—1—2 bells, done hoisting for the day.
- 2—2—2 bells, change buckets from ore to water, or vice versa.
- 3—2—1 bells, ready to shoot in shaft. (See Rule 3.)

Engineer's signal, that he is ready to hoist, is to raise the bucket or cage two feet and lower it again. (See Rule 3.) Levels shall be designated and inserted in notice herein-after mentioned. (See Rule 5.)

SECTION 2. For the purpose of enforcing and properly understanding the above code of signals, the following rules are hereby established:

RULE 1. In giving signals make strokes on bell at regular intervals. The bar (—) must take the same time as for one stroke of the bell, and no more. If timber, tools, the foreman, bucket, or cage, are wanted to stop at any level in the mine, signal, by a number of strokes on the bell, the number of the level first before giving the signal for timber, tools, etc. Time between signals to be double bars (—). Examples: 6—5, would mean stop at sixth level with tools. 4—1—1—1—1, would mean stop at fourth level, man on hoist. 2—1—4, would mean stop at second level with foreman.

RULE 2. No person must get off or on the bucket or cage while the same is in motion. When men are to be hoisted, give the signal for men. Men must then get on the bucket or cage, then give the signal to hoist. Bellcord must be in reach of man on bucket or cage at stations.

RULE 3. After signal "Ready to shoot in shaft," engineer must give his signal when he is ready to hoist. Miners must then give the signal of "Men to be hoisted," then "spit fuse," get into the bucket, and give the signal to hoist.

RULE 4. All timbers, tools, etc., "longer than the depth of the bucket," to be hoisted or lowered, must be securely lashed at the upper end of the cable. Miners must know they will ride up or down the shaft without catching on rocks or timbers and be thrown out.

RULE 5. The foreman will see that one printed sheet of these signals and rules for each level and for the engine-room are attached to a board not less than 12 inches wide by 36 inches long, and securely fasten the board up where signals can be easily read at the places above stated.

RULE 6. The above signals and rules must be obeyed. Any violation will be sufficient grounds for discharging the party or parties so doing. No person, company, corporation or individuals operating any mine within the State of California, shall be responsible for accidents that may happen to men disobeying the above rules and signals. Said notice and rules shall be signed by the person or superintendent having charge of the mine, who shall designate the name of the corporation or the owner of the mine.

SECTION 3. Any person or company failing to carry out any of the provisions of this act shall be responsible for all damages arising to or incurred by any person working in said mine during the time of such failure.

SECTION 4. This act shall take effect immediately.

A SHINGLE trust, similar to that recently formed in Oregon and Washington, will shortly be organized at Vancouver, B. C. The trust will include all mills in the Province. For some time the shingle trade has been unsatisfactory, low prices prevailing. The actual cost of production is \$1.40 per thousand, yet the sale of 2,000,000 was reported recently at \$1.15. The chief object of the formation of the trust is to regulate prices. Most of the shingle men are in accord with the movement.

Mining for Bismuth.

W. B. Roberts, M. E., contributes to the Australian *Mining Standard* an article on bismuth mining in Australia, from which we take the following:

The Degilbo division of the bismuth district of Queensland is rather remarkable for its varied geological conditions and the diversity and peculiar character of its ores, bismuth being found in the forms of telluride, sulphide, carbonate and also small quantities of "native" metal. In most cases there is a varying quantity of gold found with these ores, and in a few cases they are associated with copper, when they carry a small amount of silver.

The principal country rocks are a crystalline metamorphic slate (in places traversed by dykes of porphyry) and a coarse micaceous granite.

The first notable find of bismuth was made some six years ago in the property now held by the Mt. Shamrock Gold Company, Limited, of London. An outcrop of gossan, evidently the decomposed capping of an extinct thermal spring, was found to be rich in gold, and associated with it was a heavy yellowish mineral that on being submitted to the local analyst was pronounced by him to be carbonate of bismuth.

The circle of the old geyser was fairly well defined, the diameter being about 40 feet, with a slight underlay south-east, and this has since been followed down to a depth of 225 feet, and the ore therefrom milled yielding about 15 dwts per ton. Before the "pipe" formation was understood considerable money was expended by other companies in trying to find the combination of what they supposed to be a lode, but without success.

No regular vein of bismuth was found, but boulders of rich ore were met with occasionally and put aside, and a five ton shipment sent to London realized £160 per ton, the ore yielding in addition some 30 ounces of gold per ton.

With depth, however, the ore became difficult to treat, the gold being to a great extent chemically combined with the bismuth and telluride—in fact, a telluride of gold and bismuth—but at the same time there was too much arsenical and iron pyrites present to permit of a payable bismuth concentrate being made, the smelters in Europe declining to purchase ore that does not carry at least 10 per cent. The mill-tailings in Globo assayed from one-half to one per cent bismuth.

Whenever a clean lump of the telluride could be got it ran extremely high for both gold and bismuth. The average of quite a number of assays done by me gave about 40 per cent bismuth and 200 ounces gold per ton, and one lump of same, 10 pounds in weight, assayed 66 per cent bismuth and 2170 ounces gold per ton.

Finding that they were only getting a small proportion of their gold by amalgamation process, the company erected concentrators, and a chlorination plant, of the Newberry-Vautin type, but all attempts in the latter direction failed, owing, it is said, to the peculiar character of the ore, and they have since been realizing on the concentrates by selling them to smelters.

Some four miles distant from Mt. Shamrock, a belt of quartz reefs in granite country are being worked, the remarkable feature of them being the large quantities of sulphide of molybdenum that they carry, lumps as large as hens' eggs showing out very clearly in the white quartz, and in some cases the gold being interleaved between the flakes of molybdenite.

About 12 miles east of the Mt. Shamrock Company's property a local company, known as the Biggenden Mining Company, is operating very successfully for gold. The mine, situated about 100 yards from the contact line of the slate and granite, is primarily a huge deposit of magnetite, but as iron ores are as yet valueless in Queensland, this would not have attracted any notice had it not been for the bismuth ore found sparingly interspersed through it.

The bismuth not occurring to the extent of more than one per cent, and the sp. gr. of the two being very close, considerable trouble arose over the concentration of it, but this was overcome by the erection of a magnetic separator of the Ball-Norton type. Bismuth being diamagnetic, the material was found to be eminently suitable for magnetic concentration, the iron, in the absence of a market, being thrown over the dump.

A later development proved the existence of a large body of hornblende running parallel with and separated from the magnetite deposit by a slate fault of some 30 feet in width, and this hornblende was found to contain both gold and bismuth in payable quantities. This rock runs about one-half ounce gold per ton, and one to two per cent bismuth. From this the company pays regular monthly dividends. The body of pay ore is, so far as yet proved, about 20 feet wide by about 130 feet long, another slate fault forming the hanging wall, and underlies about 60 inches.

The mode of operating is as follows: The ore body is tapped by a tunnel, from which the cars are run out, and sent to the mill, 130 feet below, by a gravity tramway. The ore is then dumped over grizzlies, the coarse lumps going to the rock breakers, of which there are three (Dodges). From the bins it gravitates into automatic feeders (Challenge), and from them into the Huntington mills—two three and one-half foot, and one five foot being worked, and from them over copper plates, and thence to the Frue vaners, a mixed concentrate of magnetite and bismuth, running 10 to 12 per cent of the latter, being obtained. It is then dried, and run through the magnetic separator, either one or two passes being given to it, according to the quantity of iron present, the aim being to get it up to about 20 per cent bismuth. It is then put up in coarse bags, carrying 100 pounds each, and shipped, ore of this percentage netting in London about £100 per ton.

Unfortunately the market for bismuth is very limited, and the handling of the ore and metal being controlled by a "ring," only a proportionate share of ore sales per month is allowed to each of the few producing mines of the world.

Under other conditions this mine could very comfort-

ably undertake the supplying of the total demand, and if ever a question of "survival of the fittest" should arise, she will be found "right there."

The ores of bismuth are as follows: The principal ore is the sulphide (bismuthinite), 82 per cent Bi, Sp Gr 7, also carbonate (bismutite) percentage about the same. It is also found in pockets as bismuth ochre, Bi₂O₃, Sp Gr 5.5, also in combination with tellurium, as telluride, and also as native metal, in occasional nuggets, the largest of those I have seen being 12 pounds. The sulphide of Bi is very similar in appearance to stibnite, crystallizing in long, needle-like aggregations, the carbonate also very much resembling the oxide of antimony, being a dense, heavy, greyish-white mineral, with a very strong tendency to take up the strain of carbonate of copper, should there be any of the latter ore in the vicinity.

The metallic bismuth is a silvery-white metal with a peculiar pinkish shade, Sp Gr about 9, with a magnificent rhombohedral crystalline structure.

Exposed in a molten state to the air it oxidizes rapidly; in fact, it can on a pinch, be very well substituted for lead in assaying operations, the only drawback being that it is apt to leave the gold or silver scattered over the cupel in minute beads.

Its chief use is for making the various fusible alloys. Its own melting point is 507 degrees, but alloyed with certain proportions of lead and tin, it lowers its and their melting points in a remarkable manner. The assayer who forgets this fact and uses litharge in doing a gold or silver assay of an ore containing bismuth will probably be surprised, as I was, by finding the button melt in the tongs before it could reach the cupel, in a moderately hot muffle. Another curious property of the metal is its expansion of one thirty-second of its bulk as it cools, and this is availed of for alloying with type metal for giving clear-cut edges, and also in taking sharply-cut casts of engravings, etc. The expansion is so pronounced that on pouring, say, one ounce of the metal into a mold that will not allow it to expand laterally, as it cools it will crack, say half an inch of slag, and a tiny pin-point of metal will shoot up and continue to come till there is a head on top of the slag the size of a small marble.

A small quantity is also used in medicine as subnitrate, prepared by precipitating it with excess of water only from a nitric solution. A little is also used as a cosmetic under the name of pearl white.

Hartley's Meadow Lake Process.

John Clark of, Nevada City, writes to the *Transcript* as follows:

I wish to reply, through your columns, to some assertions made in a recent number of the *Coffax Sentinel* regarding the Meadow Lake mining district. The *Sentinel* copies an article from the *Placer Republican*, in which the statement is made that the late H. H. Hartley, who died so suddenly at Meadow Lake last fall, had a process for working the ore of that district successfully, but that he kept it a secret, and that with his death the process was lost. The *Sentinel* says:

"It is true that Mr. Hartley, like most any miner in that section, could save some of the gold by working the ore on a small scale, but as to his ever having a process by which the ore could be successfully worked on a large scale, we know pretty well that Mr. Hartley never did have or know of one."

"Messrs. Frank Cook and John Clark, of Sierra City, have several mines in the Meadow Lake district. For four years past they have been trying to find a way by which the rock could be successfully milled, but thus far they have met with the same difficulty that those who tried it before them met with. Of course they can pound the rock up in a mortar by hand, the same as Mr. Hartley did, and get enough gold to provide themselves with the necessities of life, but that is all they or any one else can do in the Meadow Lake district."

"Messrs. Cook and Clark, as well as the late Mr. Hartley, and many others, have set out from there to almost every mill in the world where refractory ore is supposed to be worked successfully, but the reports from every one of these places have always been the same, which was to the effect that the gold could not be saved."

Now I desire to say that Mr. Hartley promised to fix matters so that Mr. Cook and myself could have his process in case anything happened to him. In compliance with this promise, he informed Mr. E. A. Hearsey, the storekeeper at Cisco, of what the process consisted, and instructed him to give it to us should his death occur. He also wrote out the process and deposited it in Booth & Co.'s safe at Sacramento. That he had a way of working the ore successfully I am positive of my own knowledge, and the same was the result of long years of experimenting, success crowning his efforts when he was financially unable to carry on operations on a large scale, and after capitalists and moneyed mining men had lost faith in the district on account of the many failures made to work the ore. He had become a hermit almost, and, hermit-like, kept the secret to himself. But that he could reduce the sulphurets obtained from the quartz, and extract the gold, I am certain, and at a cost not to exceed \$6 or \$7 per ton of concentrates.

As to finding a way by which the rock can be successfully milled, we have solved that question by the little prospect mill we put up last summer. By crushing the ore and passing the pulp over the canvas the free gold is saved, and by then running the pulp on to concentrators the sulphurets can be separated and caught. By concentrating say 15 tons of this pulp into one ton, almost any process, even if expensive, could be employed to extract the gold profitably. Pounding the rock up in hand-mortars is too slow work for me, unless there is plenty of free gold in it, which is not the case with the most of the Meadow Lake quartz, as nearly everybody knows it is very refractory ore.

We took 1200 pounds of quartz to San Francisco to be tested on a Cornish jig. Prof. Martin also worked 200

pounds in his globe dry-ore concentrator. The results showed that if the works were at the mines, both processes would handle the ore successfully, leaving a small margin. What is wanted is suitable works near by, economical handling of the quartz, crushing it with stamps and then concentrating, after which we will treat the sulphurets by the Hartley process.

I am satisfied that the gold can be extracted in this way, and at a profit, and intend to stay with the district, notwithstanding the adverse opinions of those who think there is nothing in it.

The Coast Supply of Timber.

Statistics just completed show that the State of Washington contains 410,333,335,000 feet of standing timber—more than enough, in fact, to form a belt around the world over three miles wide. This is the first time experts have estimated the timber values of the Pacific Northwest.

During the past six months the *Puget Sound Lumberman* has been collecting authentic timber statistics, with the following results, which are taken from the proof sheets of the *Lumberman*, and show the number of feet of standing timber in the United States:

	Stumpage Value.	Number Feet Standing.
Washington.....	\$269,561,329	410,333,335,000
Oregon.....	86,685,709	236,893,255,000
Nine Southern States.....		280,000,000,000
Wisconsin.....		26,560,035,520
Michigan.....		24,140,699,199
Minnesota.....		12,749,526,000
Pennsylvania.....		7,500,000,000
Maine.....		1,500,000,000
New York.....		1,000,000,000
California.....	\$100,700,000	100,700,000,000
Montana.....	48,750,000	65,000,000,000
Idaho.....	22,500,000	30,000,000,000

Unauthentic estimates are, for Alaska, 66,960,000,000 feet, and British Columbia something over 1,000,000,000,000 feet. Of the 190,000,000 acres in British Columbia, 170,000,000 are put down by the Canadian Pacific Railway as timber and grazing lands. Computing half of this area as either grazing or inaccessible land, and lumping the balance off at the very low average of 15,000 feet to the acre, the unauthentic estimate of 1,275,000,000,000 is reached.

County surveyors, millmen and, lastly, cruisers—timber cruisers—men who go through the timber and estimate the number of standing feet of timber—have been the sources of authentic statistics in Washington and Oregon. In other States Government statistics are accepted.

The value of the "stumpage," or timber as it stands in the forest, is reckoned at current prices per 1000 feet, which are in Washington 65 cents; Oregon, 44 cents. In Minnesota the stumpage value is \$2.87 per 1000 feet, \$3.69 in Wisconsin, \$1.61 in the southern States and \$3.44 in Michigan.

All estimates given are based on minimum figures. There are 23,588,512 acres of timber land in Washington. In height, fir trees average from 200 to 400, and 100 to the first limb in many instances. In Tillamook county, Oregon, there are fir trees from 15 to 30 feet in diameter. Cedar trees that are from 12 to 20 feet in diameter and from 150 to 350 feet high, with the first limb 90 or 100 feet from the ground, are called "large" and "fine."

At present rates of consumption the Pacific coast could supply the world for 70 years. Washington's supply would be exhausted by the world in half that time.

Specifications for Road Contracts.

The appended specifications relative to road work by contract under the new law have been adopted by the Santa Barbara Board of County Supervisors, and may serve as a model for other counties where conditions are the same. Fault is found with the new law in that it does not allow bids to be advertised, opened or awarded, except at regular meetings. It is designed in Santa Barbara to make a separate contract per year for each public road. The specifications are as follows:

In the matter of letting contracts for maintaining and keeping in repair the several public roads in Santa Barbara county.

The Board of Supervisors of the county of Santa Barbara, State of California, adopt the following specifications to wit:

1. To establish a grade with sufficient round to carry off all surface water and allow none to stand thereon.
2. Keep ruts filled in, the same to be filled as soon as any portion of the road is in need thereof, and as soon as the same is dry enough to scrape and fill as aforesaid, and at all times as aforesaid to keep the roadway smooth.
3. To fill chuck holes with clay-heavy soil, or gravel only, the same to be determined and approved by the road commissioners of said supervisor district.
4. With the exception of the bridges spanning the Santa Ynez river and those in Gavioia Pass, to keep all bridges and culverts in good repair and renew them when destroyed through neglect or carelessness of the contractor; the material therefor to be furnished by the county, to be delivered in Santa Barbara, Lompoc, Los Alamos, Los Olivos, Santa Maria and Carpinteria. To keep them clear from obstructions and in good repair, and destroy or cause to be destroyed, in the months of July and August of each year, all thistles, Mexican cockleburrs, or cockleburrs of any kind, and all noxious weeds growing on any portion of the public highways or public roads in their respective districts. To cause banks to be graded, bridges and causeways to be made where necessary, keep the same in good repair, and renew them when destroyed.
5. To keep the ditches on each side of the road open and free from obstructions, and of sufficient depth and grade to carry and drain the said roads of water.
6. To keep the culverts open and also the natural and established channels for carrying off the water in low places; where culverts are necessary the contractor to put in culverts and to grade up the road that water will not stand thereon, the material therefor to be furnished by the county, delivered at the several places above named.

It was decided to call for bids per year for keeping said roads in repair for one year, two years, three years and four years, the board reserving the right to let the contract for one, two, three or four years, and to reject any and all bids; said bids to be opened by this board April 4, 1893, said notice to contain the descriptions of roads furnished by the respective supervisors for the roads in their several districts.

The San Juan Placer Region.

Cass Hite, one of the best-known prospectors and mining men of Utah and Colorado, has given the *Denver Republican* an interesting description of the San Juan country. According to his account it is not a poor man's El Dorado. He says:

Bluff City, Utah, is about 110 miles from the mouth of the San Juan river, and lies near the lower end of the fertile valleys of that stream. Ten miles below, the river enters what is called the "Fifteen-Mile canyon." At this point it cuts, at the depth of 3000 feet, through a reef of upturned sedimentary formation, known as the "Comb." Running at the base of this reef is the "Comb Wash," which heads in the Blue mountains 25 miles north of its mouth, where it empties into the San Juan river. William Hyde ran a trading post there ten years ago, trading with the Navajos. The place is called Rincon. That is as far as a road can ever be taken down the river, and is about 90 to 100 miles to where it empties into the Colorado river. From that point the San Juan enters and plunges through three canyons that are dark and appalling as the mighty canyons on the great Colorado.

FIFTEEN-MILE CANYON.

Fifteen-Mile canyon cuts through sandstone, shale and lime, and is in places heavily charged with iron and copper; in fact, so far as the whole country is concerned, it can be called ferruginous. This canyon terminates at the mouth of Gypsum creek, and from there for five or six miles the country is lower.

Then the river drops down into Forty-five-Mile canyon. It cuts through an uplift or high ridge, which on the north side of the river is called the Cedar ridge; on the south side it is called the Monumental ridge. This ridge or uplift lies alongside of Monumental valley. They both derive their name from lofty monuments which stand over that country to the number of perhaps a hundred, and which would put all natural objects in the Garden of the Gods to shame. Where the San Juan cuts through this formation, which is old red and calcareous sandstone, shales, marl and lime, for 3000 feet in length it is simply grand. Nothing I have seen in the Great Glen or Grand canyons of the Colorado river can surpass it for beauty or weirdness.

This canyon I never had a chance to prospect as I would like to have done. It cannot be approached except by boat. There are a few places where man can climb down those mighty walls. In the Forty-five-Mile canyon are very strong symptoms of coal oil. In places the oil, where it exudes through crevices and mixes with the water in the river, can be scented for a half-mile.

LARGE MESA FORMATION.

There is a large mesa formation, running north and south from the Elk mountains to the Sierra Calabasa, beyond the head of Moonlight canyon. After the San Juan leaves the Forty-five-Mile it goes for six or seven miles through a country where the surface is much lower. Coming from the south through this depression or valley is Moonlight canyon, which we named in the fall of '81, reaching it by moonlight after a weary day's toil and exploration, starved for water and the Navajos lying to us all the time as to where we would find water. The Clay Wash comes from the north and flows into the San Juan nearly opposite Moonlight canyon.

I see by the papers that they are claiming coarse gold in those places. I look upon that as an impossibility. The Elk mesa upon the north and the Mesa Calabasa on the south are entirely sedimentary formation, and all the gold that has ever yet been found in the sedimentary rock is fine gold. Coarse gold does not travel far from the leads.

That whole country has lost several thousand feet of its surface. The great process of erosion has worn the gravels, bedrock and all down, down to the sea. Gold, being soft and heavy, has naturally ground very fine as it travels.

The only show, according to my own belief, for coarse gold in that region would be in the short gulches on the north or west of the Navajo mountain, which is at the junction of the San Juan and Colorado. They head in the trachytic formation of that island mountain, and unless

they have found coarse gold in shale, marl and sandstone, then there is no show for nuggets outside of those few, little, short gulches heading up into the Navajo mountain. You ask me my opinion, and, although I may be wrong, I do not think there is any coarse gold in that country.

MUCH FINE GOLD.

But for fine gold, large areas evenly distributed, as fine gold generally is, that has a great future. That entire country is sedimentary rocks. Erosion has caused that great box-canyon country, and left them between them high mesa formations which show in the most distinct manner the great strata of time.

The stupendous belts of the sedimentary often cut 2000 and 3000 feet in depth. A stratum of quartz pebbles, many feet in thickness, constitutes one of those great blankets that cover that entire country, and with that stratum I contended for two years. I never found anything that a poor man could work, although I am convinced I know of much good gold property in that section that could be worked with good profit with capital enough to put it in working order. The gravel in that quartz stratum, the water level of the strata for miles, would suggest that it was formed by glaciers.

I had many assays made from that, and got from \$3 and \$4 to \$25 and \$30 per ton. Now, in the canyon below that immense stratum, and even upon the tops of lower mesas and basins, where the quartz stratum has deposited its dis-

PART OF SACRAMENTO COUNTY'S EXHIBIT AT THE NORTHERN CITRUS FAIR, SAN FRANCISCO.

integrated washings, I found gold every time, but it was *oro fino*.

The great canyons of the lower San Juan and the Colorado have performed the functions of mighty sluice-boxes. The fine gold and the richest of the black sands, owing to their gravity, have dragged along behind all other matter and deposited wherever they had a chance in large and small bodies, and in some instances very rich. From the mouth of Moonlight canyon it is about 35 miles to the confluence of the San Juan and Colorado. That is a very rough canyon, and with but few gravel deposits. Coming into the San Juan from the south are Moonlight canyon, Copper canyon, Foote's and East canyon, the latter being the last, and it drains everything to the east of the Navajo mountain.

GOOD GOLD COUNTRY.

That is a good gold country, and the fact that I did not strike it rich in there is no reason in the world why others may not. I drifted over on the Colorado and struck Dandy Crossing, Tickaboo and Good Hope, where I could and did live for years with a "rocker." I believe that the bed of those streams is yellow, but it is the easiest bars or deposits we are always after. The gold deposits on these streams will last for a century of active mining. It is a barren desert country, and the great mass of poor adventurers who go there will likely suffer great disappointments, as well as for "chuck."

The waters of the San Juan and Colorado rivers are hard to take out for mining and irrigation purposes, owing to the walls and banks and the rise and fall of the water in the river. Dandy Crossing is on an air-line from mouth of Moonlight and Clay Wash, about 40 miles, and by road 65, and Bluff 70 miles and by road 90 to 100. From Utah and all of Colorado north of Pueblo and Grand Junction the best road is from Green river, Utah, by Dandy Crossing, being from Green to the crossing 125 miles, and from the crossing to mouth of Moonlight by White canyon 65 miles.

The Sacramento Exhibit.

We present herewith the *piece de resistance* of the Sacramento county exhibit at the Northern Citrus Fair now in progress in the Mechanics' Pavilion in this city. The exhibit is certainly a striking one, and one of the most popular in the pavilion.

Unquestionably, there is something very proper in Sacramento modeling the chief feature of her display as she does. Historically, the choice is significant, for Sacramento men projected the first overland road, and was the basis of operations and supplies for the most difficult construction on the line. Even though the main offices of the railway are in San Francisco, Sacramento has always retained most important features of the work. Another point of fitness in the symbolism of the locomotive lies of course in the eminence of Sacramento in the great eastern fruit-shipping trade, for, though there are many terminals nowadays, Sacramento is the point of dispatch for the upper two-thirds of the State, and not seldom the products from the far south pass through her portals.

The whole range of field, garden, orchard, vineyard and household products is fully represented, and each in almost endless variety. Such an exhibit is merely an exponent of the diversity and extent of the resources of the

county, and no one was surprised that the highest awards at the fair should be commanded by such merit.

AN important decision was handed down on Thursday last by the Supreme Court at Phoenix, A. T., in the case of the Watervale Mining Co. of Chicago, owners of the Black Eagle mine, versus the owners of the Big Comet. The case originated two years ago. The owners of the Big Comet followed a vein which transversely crossed the vein of the Black Eagle, and the latter corporation began suit in ejectment.

The lower court decided in favor of the defendants, basing the finding on four decisions of the Supreme Court of Colorado and one by Judge Hallett, United States District Judge of that State, who construed section 2322, Revised Statutes, to apply to the crossing of veins on strike.

The case was appealed, the appellants relying on the doctrine that the section defines instead that owners' claims to mineral beneath the surface must be confined to the boundaries of the claim extended downward vertically, except in case of a lode whose apex runs parallel to the adjoining claim and drifts outside above the described vertical boundaries. The appellants pointed to the fact that section 2322, which applies to transverse veins, is directly opposed to the theory of the Colorado courts, and the Supreme Court took a similar view of the case and reversed the judgment of the lower court.

The decision is regarded among legal and mining men as of the highest importance, overturning the construction of mining law which prevailed since 1879, the date of the Colorado decisions.

The Weather for February.

The local weather bureau gives the following data relative to the months of February for 21 years:

The highest temperature during any February was 76° on the 22d, 1888.

The lowest temperature during any February was 33° on the 5th, 1887.

Average date on which last "killing" frost occurred (in spring), March 8th.

Average precipitation for the month, 3.71 inches.

Average number of days with .01 of an inch or more, 10.

The greatest monthly precipitation was 12.52 inches in 1878.

The least monthly precipitation was 0.24 inches in 1886.

The greatest amount of precipitation recorded in any 24 consecutive hours was 3.60 inches on the 4th and 5th, 1887.

The greatest amount of snowfall recorded in 24 consecutive hours (record extending to winter of 1884-5 only) was 3.7 inches on Feb. 5, 1887.

The highest velocity of the wind during any February was southwest 48 miles on the 22d, 1891.

Mechanical Progress.

Large Steam Boilers.

In power boilers there just now seems to be a leaning not only to higher pressures, says *Iron Age*—a tendency that has existed and exerted an increasing influence since the introduction of double, triple and quadruple expansion engines—but also toward the increase of horsepower capacity in a single boiler. It must be admitted that large boilers of any type usually generate steam more economically than small boilers of the same type. It was formerly believed that above a certain limit of capacity there was no sensible increase in economy of steam production corresponding to increase of boiler power, and it is doubtful still whether, with pressures still in vogue, after a capacity of from 60 to 100 horsepower has been reached, any notable difference would be observed between the amount of steam generated per pound of coal and the quantity made by a pound of the same fuel in a boiler of the same kind, having a capacity of say 150 horsepower. We should usually call a boiler of in horsepower small, and one from 60 to 80 horsepower large. The difference of economy between the smaller and the larger of these boilers would generally be very sensible, and it is easy to account for it. While the outer shell, from which considerable heat escapes, even when protected by good insulation, increases directly as the diameter, the holding capacity increases as the cube of the diameter, provided all the dimensions are proportionally increased. The heating surface that can be placed within this outer shell, whether in the form of tubes or flues, does not increase as the cube of the diameter. Still it may be made very much larger in the aggregate, in proportion to the outer surface, than in a smaller boiler.

But this is not all. When the pressures carried were much lower than are demanded by modern steam engine practice the surface losses were much less than is now the case; so that differences in economy are now apparent that formerly would have been too small to be considered important. Thus we now hear of orders for single boilers of 500 horsepower capacity to be used for stationary engine purposes. Such a boiler would be as large in proportion to a 60 horsepower boiler as an 80 horsepower boiler is to a 10 horsepower. There should be, therefore, a very notable economy in the use of such larger boilers with the high pressures now used.

The danger of explosion and the enormous destruction that might result from the bursting of a boiler of the large capacity now coming into vogue is pushing the sectional water-tube and safety types of boilers rapidly to the front. Such boilers can be made to withstand enormous pressure without danger of blowing up, and they can have any desired capacity within reasonable limits. That their first cost is rather more than boilers of other types has retarded their introduction, but with the high surface temperatures of modern practice their merits have become more pronounced, and the question of first cost will no longer be so controlling as it has been in the past.

Steamship Shafts.

In discussing the recent accident to the Umbria the *American Machinist* says: The main shaft of the Umbria as we have it in our mind, was 24 inches in diameter. Now it seems an enormous pressure of steam must be required to twist such a shaft as this off. It looks immense to us who spend our time on shore, but it is well known to steamship engineers that they will be twisted off. In fact, it is considered from the time of construction up that it is only a question of time when they will fail. First, the shaft must be kept within moderate limits as to diameter, in order to reduce the friction to as low a limit as is practicable. This means that such a shaft is generally made smaller than the strictest mechanical constructions would call for. It is probably proper that it should be so made. Then again, if we take the conditions under which such a ship is worked, we shall find further reasons for its failure. It is impossible that such a shaft shall be kept strictly in line. Now if we take a piece of iron—it matters not to what use it may be put—and continually bend that piece, it is only a question of time when we shall break it. This is the condition under which the main shaft of a modern steamship constantly works. As we have said before, it is never in line. It is constantly being bent this way and that way, and as surely as can be will finally fail. There is no help for this, so far as we can see. We must take the conditions as we

find them, and must meet them in the best way possible to meet them, and that is exactly what is done in the construction of the modern steamship.

Let us recapitulate. We must not make the shaft too large, or we induce undue friction, which prevents speed. We cannot put the shaft actually in line, and finally it will break, whatever its size might be. But modern science and the exercise of modern skill have done so much for us that all we expect in the event of a failure of the shaft of a steamship is some delay. We know as nearly as we can know anything, we shall keep top of the waves, and come to shore a little later, perhaps, but come there safely and properly.

It might be said that the shafts of steamships should be made so large that they would not break, but then we sacrifice speed—we put power to useless purpose, and on the whole it is wise, perhaps, to take the risk which will come of a breakdown of of this sort, rather than sacrifice the convenience and comfort secured by the speed which we get in modern steamship transportation.

It ought to be stated that the engineer corps of the Umbria experienced no serious difficulty in putting the vessel in shape to complete her voyage.

Gas vs. Coal for Cooking.

As showing the rivalry that exists in catering to and for the domestic fuel trade of the country, we append the following from the address of Captain William Henry White, president of the American Gas Light Association, at its annual meeting in Boston:

"But having granted that electricity was a great spur to our sides, and that its advance taught our patrons the need to them of a more profuse illumination than that which formerly answered their purposes, in my opinion the main cause of the advance shown in our gas output is to be traced to the pertinacity with which the introduction of gas for purposes other than lighting has been followed. I certainly am not wide of the mark in saying that many, even of our fairly large companies, are to-day, or have been during the summer season, sending out more gas for purposes other than illuminating than was sent out by them 15 years ago for every purpose. What is the inevitable knowledge that it brings to us? What is it that this so plainly shows us the future shall be? (1.) That our field is to be many times larger than any that we ever dreamed could be our portion—that is really bounded only by the limits of the habitable portion of the various communities to which we cater. (2.) That we are growing closer every day to the 'poor man' as our ally. During the past two seasons, more particularly in the last, the use of gas for cooking purposes has increased phenomenally. Thousands of cooking appliances have been placed, and, in fact, in the city of New York, it is rather the rule than the exception now that architects, arranging for the construction of large apartment houses, prepare their plans for the placing of gas cooking ranges instead of coal ranges. New and ingenious schemes or plans for encouraging the domestic use of gas have been thought out and applied. Lectures by experts in the 'art culinary' have been given, with much attention to detail; repeatedly, even in our smaller cities, prizes have been put up for competition among the matrons and maids of several towns, and now comes Cincinnati, where our ex-president, General Hickenlooper, proposes to award \$500 in money prizes, for competition by the female pupils in two prominent high-schools of that city.

"Ten years ago such schemes would have been regarded with, to say the least, marked disfavor; to-day they are accepted by us as legitimate and praiseworthy aids to the spread of our industry. This matter of increasing the day send-out will call for primarily but one important expenditure on plant account—the augmenting of holder capacity, and that expenditure will repay us doublefold, in that it will insure such capacity for all needed purposes, either by day or at night, enabling us to work more economically over the entire time in our generating plants."

FAST TORPEDO BOATS.—The famous torpedo-boat builder at Elbing, Schichau, has just attained an unprecedented speed even for this class of vessel, torpedo boats built by him for the Russian and Italian governments having reached 27½ knots on an hour's run at sea. The new British boats are to be 200 tons displacement, while the Russian boats are 130 tons, so that the former may do better by reason of greater power and greater size. The length of Schichau's boat is 152 feet 6 inches, the beam 17 feet 5 inches. She may carry 40

tons of coal in her bunkers. On trial, however, she had only 20 tons on board. The small guns carried weigh only 2½ tons; the torpedo armament, 6 tons; the crew, provisions, stores and firearms, 4½ tons; drinking water, 2½ tons; engine and boatswain's stores and reserve parts, 4½ tons—so that all the movable parts come to 20 tons, making, with coal, 40 tons. The vessel and the machinery are, therefore, very light. The shell plates are barely a quarter of an inch thick. There are two locomotive boilers, protected by the coal bunkers, supplying steam at 195 pounds pressure to high speed engines. The guaranteed speed was to be 26½ knots in the open sea, while on trial the vessel actually made 27½, or to be more precise, 27.4 knots, as a mean of one hour's steaming at sea. Schichau promises even higher results with the torpedo boats he is now completing.—*The Steamship.*

Scientific Progress.

The Medical Use of Compressed Gases.

Dr. Clement B. Lowe, in a note on this subject to the Philadelphia College of Pharmacy, remarked that within a comparatively recent period there has been introduced to the notice of the medical profession the use of compressed gases, the principal ones now being used in this way being oxygen and nitrogen-monoxide, formerly known as nitrous oxide, or laughing gas.

The medicinal properties of both of these gases have been known for many years. Experiments made upon animals have shown that the inhalation of oxygen produces no injurious effects, but the reverse; they gain in body weight through the stimulating effects upon the nutritive functions, these results being produced mainly by the effects of oxygen upon the blood through the increase and stimulation of the red corpuscles. The effects thus produced upon animals have been verified by numerous cases reported by physicians of prominence. The chief diseases in which it is indicated are diseases of the respiratory organs, characterized by difficulty in breathing, such as asthma, croup, etc.; also in the early stages of phthisis pulmonalis, in chronic indigestion, and especially is asphyxia from poisonous gases, such as carbon-monoxide, etc. In the latter case its use may be invaluable; for instance, a person has been found insensible from the inhalation of carbon-monoxide produced by imperfect combustion in a stove in a bed chamber. If the carbon-monoxide has not been present in sufficient amount to saturate all the hæmoglobin of the red corpuscles of the blood, recovery takes place, but very slowly, it being weeks or months before the patient is restored to normal health. In such a case the inhalation of oxygen would be of the greatest value, the hæmoglobin being at once changed into oxyhæmoglobin and the blood in the arteries being restored to its bright scarlet color.

The anæsthetic properties of oxygen-monoxide were discovered by Sir Humphry Davy. It was first used in dentistry by Dr. Wells, of Hartford, Conn., and more recently as a remedial agent by some of the most eminent physicians of the country, Dr. J. E. Blake and A. McLane Hamilton being prominent among them. It is also being extensively used by medical quacks under the name of compound oxygen. It should be stated that in many cases the latter gas has given better results than those from oxygen. It is stated that one of the best known of New York physicians has used more than 20,000 gallons of nitrogen-monoxide in his practice during the past two years, chiefly in the treatment of nervous diseases. He regards it as a sheet anchor in nervous prostration, insomnia, melancholia, etc.

While, as above stated, the use of these gases therapeutically is not new, the use of them in a compressed form is more recent, as, previous to the use of the apparatus devised by the S. S. White Dental Manufacturing Company, of this city, which, through their courtesy, I shall have the pleasure of showing you this afternoon, oxygen had to be made by the physician himself, necessitating the use of expensive apparatus and the loss of valuable time. Even if procured from those who manufacture it for calcium lighting (with but one exception in this city), it would taste of illuminating gas (carbureted hydrogen), on account of the same pump being used to compress both gases.

As the use of these compressed gases shall become more frequent by the medical profession, pharmacists can add to their stock these cylinders, and be ready to supply them at a moment's notice as they would any other remedy, as is already done by a member of our college.

In using the apparatus the compressed gas is first conducted into a rubber bag or a

metallic gas-receiver, from the former of which it is inhaled under ordinary pressure, the gas passing through a bottle partly filled with water. If to be used as an enema, the gas is displaced from the receiver by water flowing from a can placed about 22 inches above the receiver, and is passed through a bottle, containing warm water, to the patient.

Nitrogen-monoxide is used in the same way for inhalation, but when used as an anæsthetic, of course, the face piece as used by dentists should be employed.

Natural Selection at Fault.

J. W. Slater writes to *Science* as follows:

We are generally told by orthodox Darwinians that both the structure and the actions of animals are to a great extent dependent upon natural selection. Any organ, or any habit which is not advantageous to its species, will be, it is said, promptly suppressed as a possible danger, or at least an unremunerative demand.

Yet there are a few cases of habits which seem to have been acquired or maintained in flat contradiction to this doctrine. Every one knows that the *Felidae*, from the Bengal tiger down to our domestic mouser, when they have seized a prey do not at once kill and devour it, but either torment it or at least sit and watch it for some time before administering the fatal bite or blow. The consequence is that the victim sometimes escapes, as we all have witnessed, when pussy is playing with a mouse. One instance at least is on record where a man, struck down by a tiger, quietly drew a dagger and stabbed the assailant to the heart. This could not have been done with a beast of prey of the canine or ursine family, as they do not allow time for devising and executing such a maneuver. Hence we see that the peculiar conduct of the cats is disadvantageous to themselves, and we ask why it has not been abandoned. Certainly any cat which should at once devour any mouse or bird which it had caught would, in times of scarcity, have a decided advantage over its fellow-cats.

Similarly injudicious is the conduct of the domestic hen. As soon as she has laid an egg she at once announces the fact to all whom it may concern by her well-known cackling. What benefit is this outcry to herself or to her species? On the contrary, the outcry is heard by animals which are given to stealing eggs, and is understood by monkeys, if we may accept the evidence of La Vaillant. There again, therefore, we have a line of conduct quite contrary to what natural selection would determine.

In man there is not, indeed, a habit, but an organ which has lost its uses, yet is still developed in every child brought into the world. The outer ear was formerly provided with muscles by which it could be turned toward any sound for its better recognition. These muscles have become obsolete by hereditary disuse, so that in all normal subjects the ear is motionless. That it could formerly be directed so as the better to receive a sound will be less denied as it survives in certain exceptional individuals; but as it is absent in the great bulk of our species, the question arises, Why does the external ear not gradually cease to be developed? No one can now contend that it is useful.

THE PREPARATION OF CHROME.—At a recent meeting of the Académie des Sciences, Mons. Moissan announced that Mons. Placet had succeeded in preparing considerable quantities of chrome by electrolysis in such a manner that the industrial employment of that metal has now been rendered possible. The chrome contains 99 per cent of metal. It is, therefore, purer than that which is obtained by reduction with carbon, which gives a metal containing a heavy proportion of carburet. The industrial application of chrome is worthy and capable, Mons. Moissan says, of great extension owing to the inalterability which it communicates to the surfaces on which it is deposited. In this respect it is superior to nickel; while the alloys which it can form with the usual metals are very remarkable.

SINCE the late cholera epidemic at Havre and Rouen, the Prefect of Seine-Inférieure has been investigating electrical methods of disinfection. *Figaro*, in a recent number, has drawn the attention of the French nation very forcibly to this scheme, and it may be well if other nations devoted a little attention to the project. The process of M. Hermite, of treating sea water electrically, is the method alluded to, and M. Gautier, the writer of the article, is urgent in his suggestions that the commissions of Havre and Toulon and other ports open to infection should adopt some such means of dealing with the sanitary state of those towns.

Electricity.

Lighting Factories by Electricity.

In considering the problem of lighting a manufacturing establishment by electricity, says the *Electrical Review*, it is often found that the engine already installed to furnish power to the operating machinery has a surplus, which it may be desired to use for driving the electric-light dynamos. On general principles, however, it is always the better plan to have a separate engine or engines for this work. Sometimes, it is true, the factory owner having such power surplus in his main engine does not wish to incur the expense of a new additional engine, or there may be difficulties in the way of securing room for an extra engine. Under such circumstances, of course, there remains nothing else to be done but to take the necessary power from the engine already in use, and the difficulties of operation then to be encountered are found in the fact that the often unavoidable speed variations in the engine, due to heavier or lighter loads, according to the amount of work being done in the factory, will unfavorably affect the light. Besides this, the light will, of course, be cut off as soon as the factory engine stops, and illumination of the shops will be impossible after the regular working hours unless it is proposed to run the large engine for the lights alone, a proceeding which may be rather expensive.

These difficulties, it has been pointed out, may be avoided by the addition of an electric storage-battery plant which will serve as an electric reservoir, reducing current variations and storing up electric energy at times of surplus, to be given out again at other times when the demand for light may be at its maximum. A comparatively small surplus engine-power may, in this way, sometimes prove sufficient to do a considerable amount of electric-lighting and save the cost of enlarging the engine plant.

A sample installation of this kind was described some time ago in one of the foreign electrical journals, *Der Elektrotechniker*, and a few of the particulars there given may be of interest. In this case the shops and offices of a factory and some annexed dwelling-rooms were to be lighted, and it was desired to have light available in the offices and dwelling-rooms for some time after the factory engine was usually shut down. The shops, accordingly, were furnished with 100-volt lamps, and the other quarters with 70-volt lamps. The dynamo furnished, normally, a 110-volt current, so that, with an electromotive force of 2½ volts for each storage-battery element, the dynamo had a charging capacity of 44 elements. A 44-cell battery was, therefore, coupled up with the dynamo, a circuit-breaker being interposed in the circuit to prevent discharge of the battery through the dynamo in case the speed of the latter, for any reason, should fall off. Three mains were led off from the battery. The first wire was connected with the positive pole of the second cell and served both the 100-volt and the 70-volt circuits. The second wire was connected with the negative pole of the 43d cell and supplied current for the 100 lamps. The third wire, finally, was connected with the negative pole of the 31st cell and supplied current to the 70-volt lamps. With this arrangement there were, as will be seen, two groups, one of 42 cells and one of 30 cells. The first group furnished a current of $42 \times 2.5 = 105$ volts, and the second a current of $30 \times 2.5 = 75$ volts. The first and last cells were not included in the supply circuits. The arrangement admitted of three combinations: 1. With the lamps out of circuit, the storage battery is charged during the day. 2. Both the 100-volt and the 70-volt lamps are supplied with current by the dynamo and the storage battery together. 3. The 70-volt lamps are fed by the storage battery alone.

It is to be borne in mind that in an arrangement of this kind, the storage battery's capacity must be sufficient for the number of lamps to be supplied, and must also be designed to receive the whole of the dynamo current as charging current.

SLIPPERY TRACKS.—Some way of effectually preventing slipping of streetcar wheels on the track when the brake is applied is yet to be devised. The cold weather and snowy rails are responsible for many of the collisions and casualties which occur during the winter season. In Scranton, Pa., recently there was a sort of epidemic of collisions for a few days, chargeable entirely to this cause. The motormen claim that the custom of sprinkling salt on the rails to melt the snow and ice thereon is a good one to that extent, but a bad one in that, when the salt becomes crushed and pulverized, it makes the rails as

slippery as before. There seems to be some philosophy in this argument, and it would be well for street-railway managers to think it over a bit. In the meantime can some one not discover a way to prevent the slipping of wheels and thus remove a factor of danger in the operation of street-cars, electric cars particularly, in the winter time?—*Electrical Age*.

Distribution of Electric Power.

The utility of electricity as a motive power is one of the industrial facts added to the history of the present century. The production of electricity was a known possibility since the ancient Grecian sage developed the electric spark by the friction of amber, but its practical utilization was delegated to the modern scientist. Its application to new and diversified forms of service is now a matter of daily occurrence, with its possible developments as yet unmeasured or defined. In the telephone, telegraph and other inventions we have seen a rapid and marked advance, which in itself is of so unique a character as to make its future more a tax on our imagination than an imposition on our credence or faith.

With this mysterious force yet but imperfectly understood and its service practically crude and immature, the much that has been done presupposes the more that is as yet undone. In the world of industry its future field is broadly outlined, where, as a motive power, it is as yet in but fractional application. If, in economics of service, unit of efficiency and in security of supply and manipulation, it establishes its supremacy over present methods, the electric motor will be as ubiquitous as the chimneys of our factories and the furnaces of our mills. This is a question of time and not of faith, and the forecast suggests the establishment of systems that will make the distribution of electric power a practical art or science.

Industrial competition is more than ever urgent for higher efficiency at lower costs, and as the struggle for trade continues the necessity will become increasingly stringent. In relaxing this strained condition, electricity will have its mollifying influence by bringing the basis of motive power values to democratic levels, where the potent force will be in general and cheap distribution. Projects of this kind have materialized in local and frictional experiments which have justified their gradual and intelligent extension. What has been done in this direction is but provisional and prefatory, it being a foregone conclusion that central stations for the generating of electric power for industrial purposes will be a special industry in the near future. In the redistribution and development of industries, it is impossible to forecast its results in the home as in the mill, and with the skilled but poor mechanic, as with the man of larger means, the service of this power will be in easy reach.

In a recent discussion of this matter at a meeting of the Manchester Association of Engineers, Mr. Thwaite of Liverpool said: "The whole technical and scientific world was indebted to the German Government for fixing and determining the long-distance efficiency factor of high-pressure transmission, as this would have more effect in supplying natural force for the well-being of man than any other of the creative human efforts of the last century. The Birmingham Corporation Electric Lighting Committee had already commenced to distribute power to the ratepayers for industrial purposes, and although it might be years hence ere the power-distributing system in its entirety would come into play, that it would come was as certain as that daylight followed night." In this field, as in others where electricity has already established its special value and efficiency, its service will find a widening employment. The question of its relative merits with other forms of motive power, while leaving a wide margin for differences of opinion, in no sense is skeptical as to a bright future for the distribution of electric power.—*Age of Steel*.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISSELL, 650 Market street, Chronicle Building, San Francisco.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoops, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Anaglyph Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. TAYLOR, Pres.; LEONARD GOW, V. Pres.; H. A. JONES, 2d V. Pres.; P. GEO. GOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Secy.; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
The Cassel Gold Extraction Co., Ltd., London, Scotland, and Africa, New Zealand, Queensland, Etc.

General Office of Company:

Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingston Gold Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champ's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned Kink and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Con. Gold Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the Mac Arthur-Forrest process.

We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process.

If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ores to a fineness of about 60 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubs especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ores for this process are the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,

P. O. Box 926. Gen. Mgr. and Secretary.

"Sensible" Horse-Power Hoisting Whims.

(DAVIS PATENT.)

**PRICES REDUCED.**

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, in hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake blocks at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and sheaves, 1400 lbs.

Circulars giving Capacities and Prices furnished on application.

Dewey & Co.'s Scientific Press Patent Agency

ESTABLISHED 1860

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, San Francisco.

RUPTURE,

FILES and all Rectal Diseases positively cured, in from 30 to 60 days, WITHOUT OPERATION OR DETENTION FROM BUSINESS. Also ALL NERVOUS, SKIN, BLOOD, PRIVATE AND CHRONIC DISEASES OF BOTH SEXES. STRICTURE AND URINARY TROUBLES CURED. No charge unless cure is effected. Consultation free. Call or address for pamphlet, DR. PORTERFIELD & LOSEY, 888 Market Street, San Francisco, Cal.

Useful Information.

Abolishing London Fogs.

The London County Council has turned out to be a remarkably active and enterprising body, says the Boston *Herald*, but when it is said to be seriously proposing to take the problem of abolishing the fogs that have so long given ill-repute to that city, it would seem that it is taking a tremendous contract upon its hands, for a proposition to abolish the London fogs sounds very much like interfering with the order of nature, such as undertaking to stop snowstorms, or, like General Dvorenforth, attempting to shake rain out of the sky. But when it is considered that the horrible fogs of London are of comparatively modern date; that they did not exist two centuries ago, and that they are due to human agency, the undertaking, though still a tremendous one, does not seem unfeasible. The character of these fogs, which obscure everything with an almost inky blackness, and often make noon-day as dark as midnight, is due to clouds of unconsumed carbon poured out of thousands of chimneys into a humid, misty atmosphere, where the smoke mixes itself with the natural fog in such a way as to seem almost a solid.

The only thing required, therefore, to prevent the fogs is to provide a different method of combustion. This it is proposed to do by establishing municipal gas works, as has been done very generally in other English cities, and producing gas for fuel purposes on such a scale and consequently at so low a price as to induce its general adoption by providing the cheapest method of heating. Its use would be made compulsory if necessary to the end in view. The advantage of gas for fuel, however, would be so evident that recourse to compulsion would hardly be required. The economy of the innovation would be very great, for not only do thousands of tons of coal now pass off unconsumed in the form of smoke, but the loss caused by the suspension of traffic while the fog lasts—and they sometimes endure for days at a time—is enormous.

B. H. Thwaite makes a daring suggestion in the *Contemporary Review* in this connection. He would generate the gas in the coalfields of South Yorkshire, Staffordshire and South Wales, and transmit it in pipes to London under high pressure, as in the case of natural gas in this country. He estimated that by this means an enormous saving over the transportation of coal by rail would be effected, amounting to a total over \$20,000,000, which, after providing for interest on cost, maintenance, etc., would, while giving consumers the advantage of fuel at a price much less than that of coal, leave a very large surplus available for public improvements, including the establishment of the new system of public water supply that London so sadly needs.

A Chance for Inventors.

The Government of India is offering a number of valuable prizes for the best designs or models of a cart suitable for military requirements, to wit, a mule cart for the transport use of the British army in India. The prizes offered are five in number, and are respectively \$3750, \$2500, \$1875, \$1250, \$625, or \$10,000 in all. *Industries* says: The award will be intrusted to a jury consisting of three military and three technical experts. The question of cost being of the highest importance, the designs should give the estimated price in pounds sterling or rupees of a single cart delivered free on board in London or at Bombay, Calcutta, or Allahabad. As a guarantee of good faith on the part of the competitor as regards estimated cost, he will, if recommended for a premium, receive, in the first instance, only one-half of such premium immediately on its award. He will, however, only receive the same proportion of the other half as represents the proportion by which he may have underestimated the actual cost of the cart. It is left to the jury to ascertain by tender in the open market, or by such other means as it considers suitable, the cost of the cart to Government, and to make its award accordingly. The object desired to be attained by this competition is the production of a design, accompanied in all cases by a working model, for a military transport cart adapted to conditions which make the use of interchangeable metal parts for all important portions of the cart absolutely indispensable. The designs and models should reach the Secretary to the Government of India, Military Department, Calcutta, not later than June 30, 1893.

THE unexampled development of the advancement of electricity for street railroads is

well shown in the statistics compiled by the *Street Railway Journal*. During the year 1892 there was an increase in the mileage of electric roads of 1878 miles, a decline of 842 miles in the horse roads, a gain of 52 miles in cable roads, and a decline of 22 miles in steam dummies, thus showing how largely horse railroads have been converted into electric lines. At the close of last year there were in operation in the United States 11,665 miles of street railways, the motive-power being distributed as follows: 4460 miles horse; 5939 electric; 646 miles cable, and 620 miles steam. The number of cars in use has reached the large figure of 38,400, which is nearly 15,000 in excess of the number of passenger cars in steam railroad service. It is stated that the investment in electric roads during 1892 has been probably not far inferior to that in railroad extensions during the past year.

MANGANESE IN RUSSIA.—Manganese is found in several parts of Russia. The mineral is met with in the Government of Ekaterinoslav, but is little exploited. Manganese is also found in the Urals, in the Government of Perm, but is only worked by local capital. The Orsk mine, in the Government of Oranburg, is but in the first stage of development. The Charopan mines, in the Caucasus, are so productive that millions of poods from them are annually exported. Of 10,500,000 poods of manganese extracted in Russia in 1890, 800,000 poods only came from mines situated outside the Caucasus, which latter district exports almost the whole of its production to Great Britain. The Russian exports of manganese, which were almost nil some years ago, have largely developed of late. Between 1887 and 1890 they more than doubled, a circumstance partially explained by the blockade of ports in Chili, which temporarily suspended shipments of Chilean manganese to England. Efforts are being made to develop the mining center of Charopan. A branch line is about to be constructed connecting it with the Trans-Caucasian Railway, upon which branch transport would cost 10 copecks per pood, compared with 18 copecks, the charge for animal conveyance.

SUBSTITUTE FOR LEADED GLASS.—Some worker in glass has hit upon a novel yet expensive substitute for leaded glass. It is nothing more nor less than cut glass applied to window decoration. In one instance, a great broad sheet of polished plate has been divided into diamond pattern quarries by a series of "V" shaped grooves, cut deeply into the glass. While having all the effectiveness of lead lines, these cut figures sparkle and glow in the sunlight like so many crystal prisms, and produce beauties impossible in any ordinary leaded work.

ONE VIRTUE OF CINNAMON.—"No living germ of disease can resist the antiseptic power of essence of cinnamon for more than a few hours," is the conclusion announced by M. Chamberland as the result of prolonged research and experiment in M. Pasteur's laboratory. It is said to destroy microbes as effectively, if not as rapidly as corrosive sublimate. Even the scent of it is fatal to microbes, and M. Chamberland says a decoction of cinnamon should be taken freely by persons living in places affected by typhoid or cholera.

THE screw-propeller ferryboats have thoroughly shown their superiority since the rivers filled with ice, this being the first experience of the new boats on the Pennsylvania route across the Hudson river. While other boats are liable to have their wheels clogged and labor so hard that they are occasionally delayed to raise steam, the submerged propellers experience no difficulty whatever, and run nearly on schedule time. The large screw steamers on the sound have done equally well.

THE clouding of the inner surface of microscopic cover glasses has recently been investigated by Herr R. Weber, who finds, says *Anthony's Photographic Bulletin*, that only glasses of a certain composition are affected in this way. Those containing excessive amounts of alkali soon lose their luster in the presence of moisture, while those of a slightly greenish tint are the most stable. The moral is obvious.

ONE hundred and nine thousand locomotives are at present running on the earth. Europe has 63,000, America 40,000, Asia 3,300, Australia 2,000, and Africa 700. In Europe, Great Britain and Ireland take premier position with 17,000 engines.

THE long-distance telephone is rapidly in some ways superseding the telegraph in this country.

All Work Tested and Guaranteed!

Improved Portable Hoisting Engines

....SOLE MANUFACTURERS OF....

KENDALL'S PATENT QUARTZ MILLS.

Having renewed our contract on more advantageous terms with Mr. N. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past 14 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that is claimed for it and give entire satisfaction.

MARSHUTZ & CANTRELL.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

Adamantine Shoes and Dies

—AND—
CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplied.

STAMP SHOES.

STAMP DIES.

CARBOLINEUM AVENARIUS!

THE Most Efficient Wood Preserver.

IN USE FOR OVER TWENTY YEARS.

If you want to preserve the Timbers used in your mine from rotting and decaying paint them with CARBOLINEUM. You may rest assured that they will then remain solid. Write for particulars and prices to

CARBOLINEUM WOOD PRESERVING CO.,

319 CALIFORNIA STREET, - SAN FRANCISCO.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frus machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager. 419 California St., San Francisco.

Mining Summary.

The following is mostly culled from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Calaveras.

THE MOSER MINE.—*Calaveras Chronicle*, Jan. 28: Work on the Moser mine, situated about a mile and a half from this place, has been energetically prosecuted ever since it was bonded to the parties now in possession of it. W. T. Harris, the general superintendent and manager for this company, is well known by all the old residents of this vicinity. He has been at work about three months, and the results of his development so far more than justify the good opinion he at first entertained of the property. The developments up to the present date consist of a tunnel 325 feet in length at the south end of the mine and near the Old Lamphear. This tunnel cuts the ledge at a depth of 100 feet, showing a fine body of ore seven feet in thickness of solid quartz, besides a rich feeder six inches thick about five feet from the west wall. From tests made at various points across this ledge, and from the rock taken out, an average of \$10 per ton is a very safe estimate of the value of the rock. At the mouth of the tunnel, where the company proposes to locate its principal works, is an eight-stamp mill in process of erection. The work is in charge of that well-known and efficient mechanic, Geo. E. Woodbury of Railroad Flat, ably assisted by Mr. Wullom of Stockton. It is expected that the mill will be completed and in operation by the 1st of March. Two hundred feet north of the tunnel first described is another tunnel run through the west rim of the Moser gravel mine. In this tunnel three ledges were exposed—the first, a 15-inch ledge of high-grade ore, mostly ribbon rock of remarkable richness. Actual tests from this ledge show the rock as ranging from \$5 to \$186 per ton. This kind of rock has been shown to a depth of 50 feet. The second ledge, 25 feet from the first, is about three feet in width and shows rock of the same general character and appearance as the seven-foot ledge first described. Five hundred feet farther north the same ledges are exposed on the surface, with very gratifying prospects, and between them a large body of decomposed talcose slate containing bunches and small stringers of rich rock. This would indicate a pay chute of not less than 700 feet in length, dipping toward the north, thus insuring to the company all the dip, no matter to what depth it may reach. The company consists of the well-known wine merchants of Stockton, George West & Son, Frank E. Lane and W. T. Harris. Mr. S. S. Moser, of whom the property was bonded, retains a one-eighth interest.

El Dorado.

ORO FINO.—*El Dorado Republican*, Jan. 28: Sixteen men are employed at the Oro Fino mine on Big Canyon in the French Creek mining section. They are under the direction of Superintendent Pierce and the ownership is vested in San Francisco parties, a man named Lee being chiefly interested. The shaft is down 105 feet, and from the bottom a tunnel has been run to cut across the ledge, which is an immense body of quartz that is traced for miles—across the river into Amador county, it is said. They have run their tunnel into the ledge a distance of 45 feet without finding the wall, and unsuspended progress in that direction, being fearful that more water than they cared to handle would come in from the wall. The rock taken from the tunnel was milled profitably, and the owners seem to feel every encouragement to go ahead.

BIG SANDY.—The Big Sandy mine, near Kelsey has made some very favorable development work recently that will be encouraging to owners of similar property in that mining section, where many similar deposits exist. The mine at the surface consisted of a wide deposit of porphyry, as miners term it, a brownish-yellow matter traversed by many small gold-bearing quartz veins. At first the mine was operated by crushing the porphyry and quartz without separating and a large open cut was excavated. When the ore was thus taken out on top, it was determined to sink a shaft to see what results would be obtained when depth was reached. The shaft was commenced on one side of the vein. It has now reached a depth of 80 feet, and a crosscut reveals a ledge of nearly solid quartz bearing gold to paying quantities. The shaft will be pushed on down, and it is believed that the quartz veins will consolidate into a good solid ledge.

GREEN VALLEY.—C. T. Uhlenkamp and Geo. Weaver were up from Green Valley country last Monday. The latter has been working his mining claim again this winter, and found a nugget not long ago worth several hundred dollars. A number of pieces have been found nearly as large as a man's fist. The claim is in a wide ravine or flat and the soil very shallow. The gold usually contains quartz.

Humboldt.

HUMBOLET PETROLEUM.—*Watchman*, Jan. 23: Every turn in the work of developing petroleum in Humboldt but adds to the certainty of the deposit, confirms and makes confident the minds of those engaged in the enterprise. The latest expression upon the matter which we have is that of Prof. A. C. Hickman, who has recently made an investigation of the Garberville region. Mr. Hickman appears to be perfectly conversant with oil development in Pennsylvania, and claims that there can be no doubt of the existence of large deposits of crude petroleum of the highest character, and that its development in commercial quantities is by no means a problem—that is an accomplishment that is certain to come to pass. It now transpires that the former superintendent set

up the derrick several hundred yards south of the location selected by Mr. Clark, the expert who located the lands for the company. Prof. Hickman claims that, had the well been sunk where the location was selected by Mr. Clark, they would have struck the oil-bearing vein at the proper depth, but sinking as they did and striking it as they did at 410 feet, was too near the surface for successful service; that they should not have gone below that point in that well. He claims, however, that this well is by no means a lost venture, for it has demonstrated certain facts; it has exposed with a certainty the nature of the formation, and will be a valuable guide in locating the next well. Oil was struck in considerable quantity at 410 feet, but they thought to strike the second sand at 1800 or 2000 feet, and thus get a strong flow, but in this have failed, and are now shooting the well at the 410-foot point. Here they will undoubtedly secure at least an ample demonstration of petroleum, and with the history of this well as a guide feel certain of success in the location of a second well. The operation of shooting the well was delayed a few days this week for lack of proper materials. Meantime those most conversant with the work feel that whatever difficulty may be encountered, the ultimate result is bound to be development of petroleum.

Inyo.

PROMISING OUTLOOK.—*Register*, Jan. 28: Some rich specimens are being shown from the Georgia gold mine in Redding's canyon nearly east of town. A chunk of quartz from there now in Bulpitt's store is heavily speckled with the precious metal. Reports say that the ledge is increasing in richness as it is followed, and the owners are sanguine as to its value. Geo. F. Willis, who is working the mine, owns a half interest and holds a lease of the interests of Hill & Anderson.

PANAMINT.—*Cor. Inyo Index*, Jan. 28: The mountains bordering on the east side of Death valley, partly in Lincoln county, Nevada, southeastern Inyo and the northern portion of San Bernardino county, Cal., embracing a large territory and lying between longitude 115° and 117° west, and latitude 35° 46' and 36° 46' north, is a comparatively unknown country. Very few men have had the hardihood to brave the dangers, endure the trials and privations necessary to go through in order to prospect that section. Amargosa and Black mountains forming the eastern boundary of Death valley, have in many places never been visited by white men and possibly very little by the Indians living in the vicinity, as they have a limited knowledge of the water and topography of the country, seeming to avoid it for some reason. What little has been found out in regard to the mineral character by the few whites who have penetrated the mountains, is of a very flattering nature. Many specimens of rich gold, silver, copper and lead-bearing ores, and samples of borax, soda, lithographic stone, clays and other minerals have been found and brought in from both the mountains and valley. In consequence of the great heat of the deserts, which had to be crossed before an entrance could be made in the mountains, considerable risk attended the undertaking. In one of the canyons leading down from the Fernal range to Death valley, on the north side of the canyon, an iron-stained quartz ledge crops out for quite a distance. Some of the croppings show gold freely and are very rich. Never has there been any work performed upon the ledge and doubtless has never been seen by more than three white men, who discovered it while making their way across the mountains and valley on their way to Panamint some years ago. Stopping to investigate the extent of the discovery was out of the question, as they had no knowledge of the country and water nearly gone, contenting themselves with bringing a few samples. The pieces brought in were very rich. Before reaching water they nearly perished from thirst, and no inducement could be held out after their recovery to again cross the valley that summer. Many ledges of silver bearing quartz have been found by the float rock washed down toward the valley; some containing horn silver, others containing copper and base metals, and high grade in their character. Great boulders of lead lie exposed upon the surface, which being traced up lead to huge croppings of galena, discolored by the elements, looking like black and brown basaltic rock in the distance and when broken glisten and sparkle in the sun's rays like huge diamonds. In the past the discoverers have not been benefited by their find, as the lack of transportation and capital has prevented working and development. From assays, many were found to go from 5 to 100 ozs. in silver, a trace to over \$30 in gold and very high in lead, in some cases over 80 per cent, when galena was tested. What a source of supply it would be for the Los Angeles smelter, if the Salt Lake railroad was finished! Not only this, but other sections would contribute large supplies of ores, and upon which development has been made; many miners now having large quantities of lead ores upon their dumps that cannot be reduced for the simple reason that there is no suitable fuel for reduction, the bringing it in being too costly, and transportation of ores to where they can be worked costing from \$60 to \$80 per ton, which would eat up all profits, bringing the miner in debt. At Resting Springs, milling was attempted but soon abandoned, the ore carrying too high percentage of lead to admit of successful amalgamation. In the foothills bordering the valley, large veins resembling quartz crop out hold. To any one not acquainted with their composition, they would be taken for barren quartz ledges, but are very rich in boric acid. In the near future they will become the source of most of the supply of our commercial borax. Many varieties of fine building stone are found here, white and colored marble, red and brown freestone, slate

and other stone suitable for architectural and artistic purposes. In places where volcanic agency is discernible, red and brown-colored earthy matter has been formed which, upon investigation, might produce an excellent article of mineral paint. Clays as white as the driven snow, showing a beautiful polish on being cut, closely resembling meerschaum, and others suitable for manufacturing earthenware, and firebrick also exists here. Toward the east side of the valley, extending for several miles in length and some two miles in width, is an enormous body of nearly pure salt, looking like a great mass of ice. In places, crevices have been formed and huge pieces tilted on end, forming fantastic figures, it being of sufficient purity, after the surface has been removed, for domestic purposes. Along the course of the Amargosa river, in many places the depression is below sea level, as much as 120 feet being found at a point opposite Bennetts Holes. Large beds of extinct lakes, rich in borax, soda and other mineral salts, lie in the valley.

Lake.

THAT COAL MINE.—*Clear Lake Press*, Jan. 27: Considerable talk and some little excitement have been caused of late regarding the discovery of coal in this vicinity. We took occasion last Saturday, in company with another gentleman, to visit the supposed valuable deposit, which is located in the hills some five or six miles to the northwest of Lakeport. We found the spot where some work had been done, and also found coal indications, such as "black-jack," fire-clay and an occasional ball of sulphur. Still, the indications are not sufficient to warrant us in saying or believing that a vein of coal is imbedded near at hand. It is barely possible that a vein may be found, and yet a fortune may be expended to uncover but a small pocket. In a coal-mining region, such a prospect as has been disclosed in the locality mentioned would receive little or no consideration. We found a piece of "cap" rock which had evidently been in close proximity to coal, but whether in large or small quantity we have no means of ascertaining. The fire-clay found was similar to that usually found underlying coal beds, but of that quality known to old miners as "bastard" clay. We are well satisfied that there are many who will be loth to take out report of this reputed coal discovery as we give it, so thoroughly are they imbued with the belief and hope that such a bonanza has been found. We regret, indeed, that we cannot give a more favorable report, but this we could not do and confine ourselves strictly to truth in the premises, be the disappointment what it may. We have had much experience in the coal mines of the East, and are probably better qualified to speak on such a subject than a person who is but a novice in such matters. We would not counsel any one to spend either time or money in prospecting for coal at the point mentioned, unless he may be possessed of a great surplus of both.

Nevada.

TEN STAMPS MORE.—*Herald*, Jan. 27: The Providence Co., which has for some time past been running 20 stamps in their mill, are adding another ten, which will be ready in about a week. This is certainly encouraging.

Plumas.

GENESEE MINING ITEMS.—*National Bulletin*, Jan. 29: On Saturday A. Dragovich arrived from Genesee, where he has been superintending work on the old Cooper mine, now owned by the Genesee Queen Mining Company, whose office is at Carlin, Nev. This company has been running a new tunnel below the old one and now has driven it 75 feet. J. S. McDonald is busy driving a tunnel into the Lodi. This tunnel is now in 240 feet, but must be driven about 30 feet more to reach the desired point. On top a nice ledge of good ore exists. Not a great deal of work is now in progress at the Genesee mine. Mr. Gruss is expected to return in a short time, to resume active operations on that property. George Brandt has three men at work on the Centennial and is running the mill. On behalf of Goodhue & Hansen, a Chicago company, Mr. Dragovich is preparing to open up a gravel mine on Grizzly creek. A few days ago he let a contract to erect the necessary buildings. John Sobrero has a rich prospect above the Genesee mine. Mr. Dragovich had some of the ore with him as a sample. The extent of the prospect is not known, as sufficient work has not been done to determine that matter. This week Emrich & Swearingen resumed work on the Cosmopolitan and will drive the tunnel ahead. Geo. F. Brown is prospecting the Green Ledge. Indications are that these numerous operations will add to the life and business of Genesee valley during the coming summer.

THE SHENANDOAH MINE.—*National Bulletin*, Jan. 28: One of the historic mining camps of pioneer days is Rich Bar, at the mouth of French Ravine, of this county. Here it was that millions of gold were taken out in a few years, beginning in 1850. Among those who early went to this scene of activity and wealth was F. B. Whiting, for nearly 40 years a resident of Plumas and for 12 years her county clerk. Mr. Whiting knows the history of Rich Bar more thoroughly than any other living man. He has always contended that the fabulously rich deposits of gold on the Bar came from some great and rich quartz lode cut by French Ravine. In 1866, rich quartz float was found near the head of this ravine. This caused an examination of the hillsides, which resulted in a discovery of rich spurs of quartz, evidently parts of a lode across the canyon. Mr. Whiting organized a company to prospect the veins, but the venture proved a partial failure. In 1873 he became the sole owner. Having unlimited faith in the property, he expended considerable money in his attempts to develop it. Another company was organized in 1882, and work along the hanging-wall was resumed, many rich spurs being encountered,

but they were not extensive. Mr. Whiting was left alone again in 1883, but he continued, as circumstances would permit, the exploration work till 1888, when he organized a syndicate in Oakland and sold one-half of the property to the corporation. In the fall of 1891, a ten-stamp mill was erected and a test of the ore made, which resulted in partial success only. A short time since, the foreman began prospecting on the footwall of the lode and soon opened up an immensely rich body of ore. The vein is four feet wide and is considered one of the best propositions ever developed in the county. Gold in large quantities exists all through the vein now exposed. Mr. Whiting yesterday returned from a visit to the mine and brought with him a small sack full of samples. The piece seen by us weighed about 20 pounds. Gold could be seen all over it, and it is estimated that such ore would pay \$5000 per ton. Of course, not all of the vein is as rich as this piece, but is of high grade. Already, probably 150 tons of rich milling ore are on the dump, and there is every indication of a permanent ledge. Mr. Whiting is more confident than ever that this lode furnished to Rich Bar the wealth of gold secured by the pioneers in the early "fifties."

Shasta.

SOUTH FOAK.—*Shasta Courier*, Jan. 28: Mining matters are somewhat quiet. There has been some claim-jumping and trouble in consequence. Lewis has bought out the Eubanks, on Andrews creek, and is running some free-gold ore through the arrastre. Strecher has found a good ledge just east of the Chicago and is doing some work on the same. Dunham & Gillon are getting good ore on the Big Central. Bull continues to extract good ore from his mine and has a shipment ready. The work on the mill at Robinsons progresses as favorably as the tardy arrival of machinery permits. Wright is doing some good work on his gold ledges near home. E. E. Ballou's plant will be ready to start as soon as the balance of the machinery gets here—two or three weeks likely. Moody is running a lower tunnel on his ledge. Cooper is running in on the Hope to tap a chimney of rich ore on his north extension.

LOCAL NOTES.—Mining matters have been rather quiet the past week or two, but the presence of so many mining men from below is an indication that points to a general revival in mining matters in this vicinity. We have got plenty of good mines hereabouts, but the lack of money and muscle is the main obstacle in their development. Some small-calibered miscreant doped the Drury & Paige arrastre on Middle creek with a dose of lard, and work has been suspended for a while. The water supply is too low to furnish sufficient motive-power to run the arrastre at present. The Schroter boys began work on the old Reese mine, near town, and will get out ore for their mill. This mine has turned out some very rich rock. The storm, if it continues, will be a great benefit to placer miners, as the water supply in the creeks and gulches has about petered out. The Washington mill, at French Gulch, is still pounding away on good rock from the mine. This mine is the oldest in the State, and has probably produced more bullion than any mine in the county.

Sonoma.

VEIN EXHAUSTED.—*Sonoma Tribune*, Jan. 26: The Great Eastern quicksilver mine, southeast of Healdsburg, will close down with permanence in about a month, the vein now being almost entirely exhausted. This mine has been operated for many years and was the best paying in this part of the State. R. E. Lewis and A. Abbey are principal owners, and each realized thousands of dollars for their investment.

Tuolumne.

MILL.—*Tuolumne Independent*, Jan. 29: The 40-stamp mill at the Rawhide mine will be running in a short time, using 16 concentrators. The Black Oak mine has good developments recently, and intends to hold her own among Tuolumne mines.

Trinity.

THE TRINITY RIVER MINES.—*Cor. Journal*, Jan. 28: Just before arriving at Carr's place I met Dan Barker, who is prospecting for quartz on Maple creek, which empties into Dutch creek on the west side of the river a short distance from Carr's. He showed me several specimens which contained free gold visible to the naked eye. The tunnel is in about 70 feet, and taps the ledge about 25 feet below the surface. He says the rock will average \$25 per ton. James T. Anderson, Ed Treloar and D. C. Dedrick are interested with him in the above-mentioned claim. After leaving the Last Chance mine, I proceeded to Chapman & Fisher's at Arkansas dam. This property was at the time of the writer's visit being worked at the lower claim. Their water is obtained from Soldier creek and carried to the mine by a well-constructed, two-mile ditch 3½ feet wide on the bottom, 6 feet at the top and three feet deep. The bank is nearly 100 feet deep, and the gravel from 10 to 15 feet. A six-inch nozzle is used on the giant and the water issues from it with a pressure of 200 feet. There are two bedrock ditches—one 500 feet long and 40 feet deep, the other 400 feet long and about 50 feet deep. The sluices are 360 feet long and the undercurrent 36 feet long by 12 feet in width. Piping operations commenced several weeks earlier than usual this season; last year they did not begin until Feb. 8th. This fine property has been worked by the present owners for 21 years. The best cleanup amounted to \$24,000; the poorest \$10,000. About 25 acres of bedrock has been stripped, and there are over 100 acres left to be washed. Five men were employed at the time of our visit; eight men are employed on the average. Mr. Chapman raises on the place all the fruit and vegetables used by the family, and the writer can vouch for their excellence, as he

enjoyed the hospitality of Mr. and Mrs. Chapman, to whom he is indebted for courtesies extended. Mrs. G. S. Gribble's claim of 59 acres lies between the upper and lower claims of Chapman & Fisher, but owing to a very limited water supply, not more than about 2500 feet of bedrock is stripped in a season. This is said to be a good paying piece of property considering the small supply of water. Mr. Chapman ferried the writer across the river, and a short walk brought him to the Good Friday claim of 75 acres, belonging to T. E. Jones, Superior Judge of the county. Robt. Glover, Thomas C. Post and John S. Post. This claim was discovered about 1870, but has never been worked very much, as the water supply is very limited, being taken from the neighboring gulches and lasting but two or three months per season. At the time of our visit but one hour's run per day could be made. For the time of running it is said to pay well. A half mile below the Good Friday mine, on the same side of the river, we reach the Sberidan Bros.' property of 104 acres. They obtain their water from Simpson's gulch by about a mile of ditches and use but one monitor. There are about 1600 feet of seven-inch pipe in use. A bedrock tunnel 500 feet long carries the debris into the river. They were able to begin pining operations five or six weeks earlier this year than usual. Last year they did not commence until February 22d. Three men are employed at present, and there is about four hours of pining per day. The yield of gold is good. The next claim below on the east side of the river is that of Fred G. Haas, which is near Junction City. There are in this fine property 200 acres, 160 of which are covered by U. S. patent. Mr. Haas has been on the property 24 years, during which time he has produced many thousands of dollars. The upper ditch is 3½ miles long from Clear gulch on Weaver Bally, and brings the water to that part of the claim where he is mining now with a pressure of 380 feet. This ditch is splendidly constructed, and has a capacity of 750 inches. The lower ditch is of the same length and 152 feet lower than the upper ditch and with a capacity of 800 inches. There are three large reservoirs. The upper one in use at the time of our visit required one hour and a half to fill, and afforded a run of seven hours' duration. Four hundred feet of 15-inch pipe and two giants with six-inch nozzles are used. There are several bedrock ditches—one of 1000 feet in length and 30 feet in depth, another 600 feet long and 40 feet deep, another 200 feet long and 12 feet deep. The sluice in use at the present time is but 85 feet long, with an undercurrent 36 feet by 12 feet. The old flume on the west side of the claim is about 1700 feet long. A new flume, now in course of construction on the Oregon gulch side of the knoll, will be 442 feet long, and Mr. Haas expects to have it ready for pining operations by March 1st. Work has been progressing for several years on a knoll about 150 feet high and about 30 acres in extent, upon which there have been four distinct benches of gravel.

NEVADA.

Washoe District.

CON. VIRGINIA.—*Chronicle*, Jan. 28: Ore extraction from the 1500 and 1650 levels of Con. Virginia is now steadily continued, 450 tons having been extracted and raised to the surface during the past week. The company will commence shipping ore to the Morgan mill in a few days, and the mill will commence crushing early next month. Have extracted during the week from the 1500 level atopes and 1650 north-west drift openings and raised to the surface 450 tons of ore, average assay value of which, per mine car samples, is \$26.95 per ton. The ore bins are about full, and we will commence shipping to the mill in two or three days. The mill will commence running early in the month of February.

OPHIR.—1465 level.—The upraise started on the sill floor, on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground, 101 feet below the sill floor of this level, has been carried up 10 feet; total height, 96 feet, continuing in porphyry with quartz.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 19 feet; total length, 497 feet, and is in a harder porphyry formation.

UNION CON.—900 level.—The joint Union Con. and Sierra Nevada west drift has been extended during the week 22 feet; total length west from the joint shaft, 2867 feet. The face is in clay and porphyry.

UTAH.—340 level.—The south drift from the main west drift at a point 595 feet in from the shaft has been extended 18 feet; total length, 41 feet; continuing in vein porphyry formation. The flow of water from the face of west cross-No. 3 does not show any decrease.

SIERRA NEVADA.—West crosscut No. 2 from Kenoeha tunnel, started from north drift, 800 feet in, has been advanced 26 feet; total length, 620 feet; face in porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 22 feet; total distance west of the joint shaft, 2867 feet; face in porphyry and clay.

ANDES.—On 420 level north drift from east crosscut No. 1, north, was advanced 14 feet; total, 63 feet; formation, principally quartz.

GOULD & CURRY.—200 level.—During the past week, west crosscut No. 5, started 432 feet from main west drift, has been advanced 12 feet, passing through hard porphyry; total length, 270 feet. On the Suro tunnel level the joint north drift with the Savage Co. has been advanced 18 feet; total length, 858 feet; face of drift in hard porphyry.

BEST & BELCHER.—900 level.—West crosscut

No. 3 has been extended 20 feet through porphyry; total length, 107 feet.

EAST BEST & BELCHER AND NORTH GOULD & CURRY.—Drifting is being continued and quartz is being passed through that looks well.

HALE & NORCROSE.—1800 level.—West crosscut No. 1 from the main south drift was advanced 20 feet; total length, 75 feet; face nearly all quartz. No. 3 west crosscut from main north drift was advanced 20 feet; total length, 272 feet; face in porphyry. West crosscut No. 4 from main north drift was advanced 12 feet; passing through some quartz that contained small bunches of ore; total length, 122 feet; face in porphyry.

CHOLLAE.—The north drift from the south line, 550 level, is out 117 feet; face in low-grade quartz. Are retimbering the two north compartments of the main shaft. The east crosscut from the north drift, from east crosscut 160 feet south of north line, 930 level, is out 33 feet; face in porphyry.

POTOSI.—The east crosscut opposite the Potosi winze, 930 level, is out 283 feet; face in hard porphyry. South drift from top of raise, 1000 level, is out 74 feet; face shows five feet of quartz containing bunches of good ore. The north drift from top of raise, 1000 level, is out 24 feet; face is in porphyry and low-grade quartz. Are grading and timbering the connection between the northwest drift from the Ward shaft, 1800 level, and Potosi winze. Extracted and sent to the mill the past week 426 tons and 250 pounds of ore from the 550, 930, 1100 and 1150 levels. Milled during the week 426 tons; on hand at mill, 80 tons and 1250 pounds. Average battery assays, \$24.51. Average car sample assays, \$25.64.

BULLION.—The east crosscut, 100 feet north of top of raise from east crosscut, 320 feet north of south line, 1300 level, is out 50 feet; face is in porphyry and quartz. The west crosscut from the north west drift, 300 feet south of north line, 1800 level of Ward shaft, is out 220 feet; face in quartz and porphyry.

APEX.—Since last report have made connection by an apraise from the tunnel level to the bottom of incline, thereby obtaining a continuous current of fresh air throughout the mine, insuring us better facilities for rapid exploration of the mine on this level. The samples of ore from bottom of incline give an average assay of \$81.42 in silver and \$139.73 in gold; total \$221.15.

WARD SHAFT.—There has been no work done on the 1800 level of the Alpha and Exchequer during the week. The west crosscut from the northwest drift, 300 feet south of north line of the Ward shaft, 1800 level, is out 200 feet; face in quartz and porphyry. Are grading and timbering the connection between the northwest drift from the Ward shaft, 1800 level, and the Potosi winze.

EXCHEQUER.—Putting of pressure pipe in the Ward shaft is nearly completed.

ALPHA.—Putting of pressure pipe in the Ward shaft is nearly completed.

KENTUCK.—Have continued to extract about 3 tons of ore per day from the 7th floor above the east crosscut on the 160 level. Shipped to the Brunswick mill 129 tons of ore.

OCCIDENTAL.—The main north drift, 750 level, has been extended 16 feet; total distance from No. 1 winze 623 feet. The drift continues in low-grade ore. No. 2 winze from south drift, 750 level, is down 28 feet in low-grade ore. The main south drift, Suro tunnel level, has been extended 19 feet in hard porphyry.

NEW YORK.—Are extracting from 10 to 12 cars of ore per day; car samples averaging from \$25 to \$30 per ton. Are repairing southwest drift from the shaft, 850 level. Shipped to the Washoe mill during the past week 132 tons, 1132 pounds of ore; milled during the week 132 tons 1132 pounds ore; on hand at mill, 60 tons; average battery assays, \$30.19; average car sample assays, \$29.70. Shipped to U. S. Mint, Carson, 186 pounds of crude bullion.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 3 feet; total distance from north line, 36 feet. All underground work was stopped for three days during the past week on account of Justice Co. making repairs to the surface machinery.

Tuscarora District.

NAVAJO.—*Times-Review*, Jan. 28: No material change in the stope since last report.

BELLE LAKE.—The stopes above the 250-foot level have been extended northward in good ore up to the break. Good ore is now making south of the apraise.

NORTH BELLE LAKE.—The stope above the south 400-foot level and those above the north 300-foot level, are yielding about the same.

OREGON.

PROSPECTING.—Ashland *Tidings*, Jan. 27: From the amount of prospecting already under way in the mountains about Aebland it looks as if a custom quartz mill will be so imperative a necessity here soon that one must be put up. C. H. Veghte has made a proposition which is talked some on the street. Mr. Veghte already has a 40-horsepower engine, and agrees to set up and run a first-class five-stamp mill provided he is guaranteed the work of crushing 500 tons of rock at \$5 a ton. Somewhat of a sensation was made last Tuesday by the exhibition of the richest piece of quartz yet shown here—a little piece about half gold, which is said to have been found by the wife of Dr. H. T. Inlow in their dooryard on their little farm east of Bear creek. It may have come from a ledge there, or from the blue gravel deposit known to exist under the hills on the east side of Bear creek. John H. Real, C. H. Hosley and others went over with pick and pan to do some prospecting there yesterday. Keno, Klamath county, is the latest seat of gold excitement. A settler named Took, on the south side of Klam-

ath river, about 1½ miles from Keno, was digging a well, and at a depth of 60 feet he struck a formation from which he panned out \$1.50 in gold with an ordinary skillet. The gold was probably from the stratum of blue gravel which underlies a large portion of the lake and Klamath river country, and it may lead to the development of some good drift mines there. C. H. Hosley, M. L. McCall, Destin High and George Engle have located a claim angling from the west side line of the Ashland Mining Company's 4500-foot claim, and they believe they are on the main lode of the Ashland mine, the A. N. King lode, better known as the Patton lode, from the Patton extension of the King claim. Surveyor McCall ran the lines of the new claim Tuesday, and it is christened the Nancy Hanks. Wallace Rodgers and J. M. Hocker are at work running prospect cuts upon the claim. One day last week Messrs. Legg & McDonald, of Foot's creek, tired of working over ground which had for a long time failed to produce anything of consequence, went farther up the stream, taking out a few wheelbarrow loads to test the diggings. The very first washout produced a nugget of "old-channel" gold weighing \$170. In addition to this the wheelbarrow experiment panned out about \$6 in legitimate washing. The placer themselves are by no means completely washed out in southern Oregon. One of the largest straight string of mining claims yet located near Ashland is upon what is called the Blue Lead. It is a continuation of the ledge upon which Roper, Carter & Mills have sunk a prospect shaft on the hill in town. It is traced by a capledge on the surface for several miles in a direction nearly due south, and 13 claims have been located on it already. George Fendall is one of the locators, as are also railway mail clerks Knowles and Bangasser, of the Portland run. Mr. Knowles got a fine prospect one day this week from a piece of surface float from the ledge. Will Q. Brown, of Riddle, now employed by the large company to whom he sold his nickel mines near Riddle, was on Wednesday's south train, going to San Francisco. Mr. Brown says the machinery for the reduction works is at the Riddle railroad station, but cannot be hauled to the mines until the roads improve. It will be summer before smelting operations are begun, but when the mining is started once it will be upon a large scale. There is abundance of the nickel ore in that region, and the demand for the metal is good, since the approval of the nickel-steel armor plate for naval use.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JAN. 24, 1893.

490,265.—FRUIT STONER—J. S. Briggs, San Buenaventura, Cal.

490,272.—PENCIL SHAPEFENER—Geo. Diez, Santa Clara, Cal.

490,276.—PLOW—D. B. English, Guerneville, Cal.

490,608.—WRAPPING MACHINE—I. R. Hutchinson, Fresno, Cal.

490,609.—RIVET FEEDING DEVICE—J. H. Martin, Oroville, Cal.

490,610.—HORSE DETACHER—Wm. Mather, Sebastopol, Cal.

490,358.—ELECTEICAL MUSICAL INSTRUMENT—A. Montanelli, Portland, Or.

490,630.—ELECTEIC CONDUIT—E. L. Ransome, Oakland, Cal.

490,631.—CONCRETE MIXER—E. L. Ransome, Oakland, Cal.

490,632.—CONCRETE DISTRIBUTOR—E. L. Ransome, Oakland, Cal.

490,362.—FIRE ESCAPE ATTACHMENT—A. J. Rich, S. F.

490,400.—THREE WHEELED CARRIAGE—G. Rouy, Redlands, Cal.

490,617.—RATCHET TRACOR—Alfred Taylor, S. F.

490,528.—BEIDGE FOR MUSICAL INSTRUMENTS—Geo. Wooster, Fort Apache, A. T.

The following brief list by telegraph, for Jan. 31, will appear more complete on receipt of mail advices:

San Francisco—Louise Ericson, bicycle bell; Lorenzo O. Granger, trousers stretcher; George Johnson, ore concentrator (2). California—Melford D. Arms, San Diego, wood waterpipe; James S. Dunham and E. D. Middlekoff, Stockton, lemon-squeezer; Thomas H. Edwards, Lathrop, vehicle axle gauge; Alonzo Fisher and G. H. Priestley, Stockton, horse-hitching device; George W. Ingersoll, Stockton, grain-saving device in threshing; Norton H. Fine, Eureka, rope leader for winding drums; Albert O. Quimby, Fresno, gate hinge; Edward G. Smith, San Jose, electrical pressure indicator for steam gauges; Samuel R. Smith, Colusa, step-ladder; Charles W. Winston and F. Throop, San Gabriel, orchard plow.

Washington—John Fishburn, Walla Walla, safety valve for water gauges; Ernest Nichoff, Tacoma, egg puzzle; Andrew F. Fugb, Palouse, fabric-tuning implement.

Nevada—John W. Cummings, Gold Hill, electric bell.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

BEAKE FOR HARVESTERS.—Christopher Gratian, Stockton, No. 490,197. Dated Jan. 17, 1893. The object of this invention is to provide a powerful compressor-brake for traveling harvesters, the parts of which are so mounted that

the brake is applied to opposite sides of the main driving-wheel, the shoes acting directly upon the projecting ribs, which extend radially outward from the rim of the wheel for the purpose of giving the wheel a sufficient hold on the ground over which it travels to drive the machinery connected with it. These machines are hauled by from 18 to 24 horses, and when the team becomes unmanageable, it is absolutely necessary to have some effective means for checking the speed of the machine, and through it controlling the team. This brake must preferably be applied to the wheel which drives the machinery and which has projecting ribs upon its face; and as there is no smooth surface of the rim for the proper application of a brake, it is a difficult matter to contrive such a brake as will be effective. The faces of these driving-wheels are from 16 to 20 inches in diameter, the ribs or grousers extending entirely across from one side to the other. This new brake can be applied to such wheels satisfactorily.

ADJUSTABLE ROCK-CRUSHER.—John P. Simmone and Wm. J. Holmes, S. F. No. 490,215. Dated Jan. 17, 1893. This invention relates to that class of rock-crushers in which an oscillating crusher-head is mounted within a shell, said head being carried and driven by a shaft which has a vertical adjustment, to regulate the position of the crusher-head within the shell and provide for reducing the rock to different sizes. The object of the invention is to provide a simple, economical and effective adjusting device for the crusher-head shaft, which can be readily operated, requiring the removal or change of none of the parts, accessible easily from the outside, and preventing the escape of the oil from the bearing box of the step on which the shaft rests. The adjustment of the shaft can be quickly accomplished from the exterior, and the adjustment can be regulated to a nicety.

DRAFT-EQUALIZER.—Peter V. Schandoney, Sacramento, No. 490,214. Dated Jan. 17, 1893. In hauling traveling harvesters upon the field, it is customary to attach large teams consisting of as many as 24 or more animals to haul the apparatus. These teams are usually hitched six or eight abreast and in three or more series, one series ahead of another. The attachments are made by means of draft and equalizing bars and singletrees attached to these bars, but as the animals all have different rates of walking, it is impossible to make them all travel alike, and by the means which are now adopted for connecting them with the load, it is equally impossible to bring an equal share of the load upon each animal or series of animals. Some of them being attached directly to the draft-bar of the machine, whenever the load is started they pull upon the whole weight of the apparatus, and the strain is unequally divided. This invention consists in the employment of connecting chains by which the draft-bars are so united as to yield to irregular pulls by different parts of the team, and thus counterbalance these pulls and practically divide the draft equally among all the animals of the team.

HOISTING AND CONVEYING MACHINERY.—Frank C. Birch, S. F., assignor of one-half to Louis Rosenfeld, N. Y. No. 489,785. Dated Jan. 10, 1893. The invention relates to that class of mechanism designed for hoisting material from a given point, conveying it thence to another point and there lowering it. The object of the invention is to provide simple and effective means capable of easy and accurate operation, for hoisting coal and other material from given stations, conveying it rapidly to another station, and there lowering and delivering it gently, whereby breakage is avoided. The invention consists in the novel construction, arrangement and combination of the traveling trolley and the means for operating it and hoisting and lowering the bucket or tub to and from said trolley.

HORSE-DETACHER.—Wm. Mather, Sebastopol, Sonoma Co. No. 490,610. Dated Jan. 24, 1893. This invention relates to the class of devices for attaching or releasing horses from the vehicle to which they are hitched, when, for any purpose, as by reason of running away or other dangerous conduct, it becomes necessary for the safety of the occupant to release the animal. The invention consists, in connection with the whiffletree and its support, of a detachable connection between them and means for holding said whiffletree normally in place and tripping it when required. It also consists in the novel construction and arrangement of the detachable connection between the whiffletree and its support, and in the means for holding and for tripping it.

RATCHET-BRACE.—Alfred Taylor, S. F., assignor of one-half to Michael Cusack and Frank Knobloch. No. 490,617. Dated Jan. 24, 1893. This is a device for operating drills and similar mechanism in which the drill is caused to advance by the movement of a lever. It consists of a mechanism whereby an approximately continuous rotary motion is given to the drill by the reciprocation of a lever arm, and in certain details of construction.

RIVET-FEEDING DEVICE.—John H. Martin, Oroville, No. 490,609. Dated Jan. 24, 1893. This is part of the machinery for making sheet-iron pipe, and is designed to facilitate the riveting of the pipe. The object of the invention is to provide a simple and effective attachment to a pipemaker's stake, whereby the rivets are automatically supplied and forced successively to position to be readily introduced into the holes in the pipe, said attachment in no wise interfering with the operation of nipe-making or being in the way of the pipe-maker's stake.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner..... \$550, f. o. b.
 " " " Improved Belt Frue Vanner 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CALIF., Dec. 15, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.
 No. 132 Market Street. - - San Francisco, Cal.

RISDON IRON WORKS,

Cable Address, "RISDONS."

S. E. CORNER HOWARD AND BEALE STS., SAN FRANCISCO, CAL.

IMPROVED MINING, MILLING, MARINE AND OTHER MACHINERY OF ANY REQUIRED MAGNITUDE.

A COMPLETE STOCK OF CORLISS, AUTOMATIC AND SLIDE-VALVE ENGINES ON HAND.

Water Works for Town Supply,
 Irrigating Plants,
 Electric Lighting and Electric Road
 Machinery,

Smelting Ores.

Smelting can only properly be carried out on special ores of lead and copper, like the carbonates, which reduce readily, or by a careful regulation of charges carrying lead or copper in other forms, and proper intermixture of fluxes. There are in some localities ores of both copper and lead which run down in furnaces with little addition except the necessary fuel; but sulphureted ores (copper pyrites and glauco and galena) cannot be so easily disposed of.

Omitting the complicated methods employed in large reduction works, the following are the methods used in mining camps:

First—The simple melting, in stack or water-jacket furnaces, of carbonates of lead or copper, or metallic copper ores. Some flux is usually required for the gangue rock, iron or lime if quartz, or quartz if too limy.

Second—Matting or running the minerals out of the rock, not in a fully metallic condition, but as a concentrated mineral or matte. This operation is conducted also in a stack or water-jacket furnace, usually after a partial preliminary roast. The matte is afterward refined.

Third—Partially roasting galena ores, oxidizing the lead and driving off much of the sulphur then a reducing smelting, in which the oxidized lead reacts on any sulphides remaining, and only metallic lead results. Here, as in the first division, proper fluxes must be added to slag off the waste rock and retain all the fluid in the furnace.

Fourth—The addition of iron ore, or roasted iron pyrites, to galena ores in smelting; the iron capturing the sulphur of the galena and leaving metallic lead.

A general description of the principles involved in the ordinary processes of smelting is all that is intended here, but the success of the last three methods depends on a proper mixture of ores, proper roasting and adjustment of fluxes. The cost of smelting ores varies from \$6 to \$25 per ton, and the yield of the ores thus treated is from 90 to 98 per cent of their assay value. On this page is given an engraving of the wrought-iron sectional water-jacket furnace, built by the Risdon Iron Works of this city. Sections may be added to this furnace to increase its capacity, as the output of the mine demands.

by over 300 installations in Europe, in deep mines, city water works (notably in the city of Paris) and for every pumping and compressing service. These pumping engines are to be supplied to the city of Boston, Mass., and Fraser & Chalmers are installing the first Riedler mining pump in the United States for the Boston & Montana Co.

A Set-Back to California's Petroleum Interests.

While California gives a small annual output of petroleum, as compared with Pennsylvania, New York and Ohio, it ranks with West Virginia and Colorado, and stands about sixth on the list of States in total amount produced. One company alone in this State has a capital of \$5,000,000 invested. The oil fields are mainly in Southern California and are being persistently developed so that the annual product is on the increase. The petroleum industry is destined to be a most important one in this State and should be encouraged. The Stewart mining bill now pending in Congress will, however, if it passes in its present form, be a great drawback to the industry not only here but everywhere in the United States. One of the provisions is that not more than 40 acres of petroleum ground can be included in the same application for patent. This would involve annual assessment work on every forty-acre tract, and a separate expenditure of \$500 before patent could be applied for. As the companies must have large areas on which to prospect, an immense useless expenditure is thus forced upon them. All the formalities for each forty-acre tract would have to be complied with, and they could not bunch a number of claims in patent proceedings. The passage of such a law would work irreparable injury to this industry and the interests involved have sent an agent to Washington to place the matter in the right light before Congress. The bill has, however, already passed the Senate and gone to the House. The Senators and Representatives from the other oil-producing States should assist the Californians in removing the obnoxious clauses from the bill.

THE Senate Committee on Capital and Labor has reported favorably on the bill limiting a day's work in logging camps to ten hours. Also the bill to prevent contractors reducing the pay of employes on public works below the classification prescribed by the Board of Supervisors. Also the bill to compel corporations to pay their employes at least once a month.

SENATOR STANFORD has authorized the appointment of a Professor of Electrical Engineering and the equipment of a laboratory for the carrying out of the work of that department. The new power-house at Palo Alto

offers an excellent location for the dynamos near the source of power.

At Roslyn, Wash., the finding of a large vein of coal the other day, was announced by hoisting the American flag over the shaft tower.

SAN FRANCISCO received in January 115,360 tons of coal. Of this 47,537 tons came from British Columbia.

WROUGHT IRON SECTIONAL WATER-JACKET FURNACE.

This has 5½ inch and 8-inch plungers, 16 inch and 25-inch steam pistons, all 24-inch stroke. Its duty is 900 gallons per minute, lifted 600 feet.

THE Southern California Smelting and Refining Company, at Los Angeles, has begun the work of preparing ground for a smelter, and expects to have the machinery in place and ready for operation early in April.

RIEDLER PUMPING ENGINES.

Messrs. Fraser & Chalmers of Chicago are introducing into this country mining pumps and compressors of the Riedler type, of which they have control. The salient feature of these pumps is positive closure of the valves, which is so effected as to obtain the full lift, with increased speed, greater simplicity of construction, smaller number of valves, reduced wear and improved efficiency. These advantages over the usual type of construction are proved

TABLE OF CONTENTS.

ILLUSTRATION.—Wrought Iron Sectional Water-Jacket Furnace, 81.
 EDITORIALS.—Smelting Ores; A Setback to California's Petroleum Interests; Riedler Pumping Engines; Miscellaneous, 81. Comment; Coal and Iron on the Pacific Coast; The Stewart Bill and the Drift Mines, 82.
 CORRESPONDENCE.—Ancient Gravels of Siskiyou County, 85. Educated Engineers and Amateur Experts, 86.
 MECHANICAL PROGRESS.—Saying by Firing with Oil on Steamers; Big Locomotives for Mexico; Cost of Naval Vessels, 87.
 SCIENTIFIC PROGRESS.—Runioke's Process for Smelting Silver-Lead Ores Containing Zinc; New Process for Making Gas; Testing Oxygen; The Action of Alkalies on Glass, 87.
 ELECTRICITY.—An Electric Torpedo Detector; Pruyn Elevated Electric Railway; The Naval Search-Light, 88.
 USEFUL INFORMATION.—Cost of Street Cleaning; Before the Clermont; Mustard; Thirty Miles an Hour, 88.
 MISCELLANEOUS.—The Stewart Mining Bill; Colliery Disasters, 85. The Woods of Washington; Notes on Palms, 86. The World's Fair Yachty; How the Telephone is Managed in Roumania; Railway Mileage; Oil Lands and Mining Laws, 90. Borax; The "Bally" Cam for Stamp Mills; Free Coal and Iron Wanted on the Pacific Coast, 82. Coast Industrial Notes.
 MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings, Assessments, Dividends, Etc., 95.
 MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific States and Territories, 93-94.

Comment.

The paper on "Cable Surveys from California to the Hawaiian Islands," read by Lt.-Commander Z. L. Tanner, U. S. Navy, at the meeting of the Geographical Society of the Pacific, January 23d, was a very interesting document. It gave an excellent conception of the ocean floor, and the varying formations disclosed by the sounding-lead, as well as the difficulty of handling a ship tossing on the surface, while soundings are being taken at great depths. The feasibility of a cable-line to the islands was clearly demonstrated. This paper has attracted much attention, in view of political developments now taking place in Honolulu, as it is evident that telegraphic connection with that city is a necessity to the United States. If any definite action is taken which places the islands under the American flag, a submarine cable will be one of the first necessities. It would hardly do to leave those islands in the isolated position in which Alaska has been left, with respect to means of communication.

The Dakota tin mining business seems to have fizzled out like that of California. Superintendent Childs of the Harney Peak Tin Company has just returned to Deadwood from New York, and by his orders the mines of the company have been closed down indefinitely, throwing 300 or 400 men out of employment. The suspension caused great surprise throughout the Black hills as recent reports of the operations were of the most encouraging nature. Superintendent Childs refuses to give any information, except that the suspension will be permanent. This ends all the talk about the expected tin product of this country. No money has been made out of the operation either in this State or South Dakota. In fact the deposits never came up to expectation in quantity. Tin has been known in both the regions for many years and if the deposits had been at all as publicly represented they would doubtless have been worked systematically long since.

The cars on the new electric roads in this city and Oakland are run at a much higher rate of speed than are the cable-cars, more especially when on the outskirts of the cities. There have been several accidents recently because the cars could not be stopped quickly when running at a rapid rate. At all street-crossings there is danger of collision. The methods of braking ordinarily in use are inadequate, and there should be some restriction of the rate of speed unless means are adopted for bringing the cars quickly to a standstill. Air brakes for this class of cars have been tested recently on the Oakland, San Leandro and Haywards electric line and seem to have proved successful, so there is apparently a remedy if the companies will adopt it. The cars should not be permitted to maintain a dangerous rate of speed unless they adopt some

mechanical appliance by which they can be brought under control within a reasonable distance.

A lot of people at Wheatland, Yuba county, got together the other day, called themselves a mass-meeting, and adopted resolutions, which they forwarded to Congress, in which they viewed with alarm all efforts to secure by legislation the restoration of hydraulic-mining, and protesting against any modification of the penal clause of the Caminetti bill. Of course they had never read the Caminetti bill, did not understand its provisions, or that the miners only asked that the penal clause be suspended until the Commission could give them licenses to mine. On general principles, if the miners wanted something they opposed it. A week before, six miles from this same Wheatland, W. P. Lepp, of that town, found on the Frank Hunt place a nugget of pure gold valued at \$496.13. A month before the same man found within 20 feet of the same spot a nugget of \$264. Two years ago a former owner of the ravine picked up a lump of gold weighing \$263, and many smaller nuggets, weighing from \$1 to \$20, have been found at different times. The finding of the last large nugget has created quite an excitement in Wheatland. There is some talk of sending it to the World's Fair. The people of Wheatland ought at the same time to send to the World's Fair their resolutions against gold-mining in general. They would fit well with the nugget.

R. I. Thomas of Nevada county has earned the admiration and thanks of the mining community for the manner in which he opposed the bill increasing the fine in debris contempt cases. After his masterly speech, his motion to strike out the enacting clause was adopted by a vote which must have astonished the antidebris people. So that is the end of that measure, thanks to R. I. Thomas.

The Ford hydraulic-mining bill passed the Senate without amendment on Thursday by a vote of 37 to 2. This is the bill which permits hydraulic mining when it can be carried on without material injury to navigable streams. It also defines hydraulic mining. The two clauses are to be amendments to the code.

The Stewart Bill and the Drift Mines.

It would seem as if this Government objected to the existence of gold in gravel, were ignorant of its presence in that form, or desired to prevent miners from obtaining it except in mother quartz. The laws have almost obliterated the hydraulic mining industry, and now threaten that of drifting, and both of these branches depend on the presence of gold in gravel. The rulings of the Departments are such at present that it is practically impossible to obtain patent to drift-mining ground until it is worked out. Capital will not invest in land to which there is no title, and no title can be obtained in advance of the actual discovery of gold. As tunnels several thousand feet long are necessary to tap the auriferous gravel channels under the lava-capping, these must be run before the actual discovery, and all the work done in ground to which there is no title. Then when the gold is found and taken out no patent is wanted. All this is the veriest nonsense but it is department-made law and the miners must submit to it. The companies spend a hundred thousand dollars in or on a tunnel to open a channel, but the Department will not recognize a channel until it is absolutely found. Meantime an agricultural claimant may take up the surface and prohibit the miner from running his tunnel under the ranch. It is no wonder that the drift-mining interests of California languish under such circumstances.

And now comes another possible restriction in the provisions of the Stewart mining bill which has already passed the U. S. Senate and gone to the House. It cuts down the amount of placer ground which may be applied for in a patent to 40 acres. This would involve annual expenditure on each 40 acre tract, and a total expenditure of \$500 on each before patent would be applied for. In this class of mining the development of a large tract is usually done by a single tunnel and drifts. Assessment work done upon the surface of such properties is absolutely valueless as a rule. The sinking of a shallow pit upon each lot in a barren volcanic capping would be fruitless and a waste of time and money. The bill also calls for \$10 worth of annual labor on each 20 acres, but only 40 acres may be patented on one claim.

To justify the great expense of opening these deposits, it is necessary that the individual or company running the tunnel should own one or two miles in length of the pay channel. Owing to the uncertainty of the course of the channel, this involves the holding of from 500 to 1000 acres of ground, or even more. It is customary to take this up in 160 acre tracts and bunch adjoining tracts on application for patent.

The injustice of the proposed law as it refers to drift

mining in this State was called to the attention of Senator Stewart at the time of the introduction of the bill in 1889, but he has not seen fit to make any change in the provisions. There are no drift mines in Nevada, where the Senator comes from; in fact, California has about all there are, so it will suffer most. Our own Senators in Congress have probably paid little attention to the bill, considering the mining interests safe in Senator Stewart's hands. But the bill as it stands affects seriously not only the drift mining, but the petroleum interests of California, as pointed out elsewhere in the PRESS. It places restrictions upon these industries, which necessitate a large and useless expenditure, to no good purpose whatever. There is no distinction made between surface or exposed placers and those, like the drift mines, covered by the lava-capping of the "divides" of California. That there should be a distinction is apparent to any one familiar with the subject. Our lawmakers, however, seem to have only a superficial knowledge of these subjects, and will scarcely take trouble to investigate them, when asked to by those directly interested. Between congressional laws, department rulings and court decisions, the gravel-mining interests of California are having a hard time of it.

Status of the Mining Bill.

The Caminetti hydraulic-mining bill passed the Senate on the 4th, and went back to the House for concurrence. Having been given an advantageous position on the calendar by unanimous consent, it was called up without opposition, and it was tacitly understood, apparently, that there should be no lengthy discussion, that matter having been arranged beforehand by Felton and Stewart, who had made up their minds to make up for all the time lost on account of the wait for the arrival of Judge Niles Searles, the representative of the State Miners' Association. There was only one voice heard in opposition, that of Senator Cockrell, who has taken upon himself the task of watching the treasury doors for the Senate. He objected to the appropriation of \$15,000, and spoke briefly on that point. Senator Felton made a brief explanation of the measure, and without further debate the bill passed. It now devolves upon the committee to see that the amendments are concurred in at once, or, that failing, to have the conferees arrive at an agreement without delay.

On Tuesday the bill was called up in the House by Mr. Caminetti, and it was sent to a conference, the House non-concurring in the Senate amendments. When the conferees have agreed, the bill will come under the head of privileged matter and will be finally passed in both Senate and House without delay. The conferees are Stewart, Felton and Mills for the Senate and Cowles of North Carolina, Caminetti of California, and Townsend of Colorado for the House. The conference committee is to consider a modification of the Berry penal clause, but whether they will adopt it or not is not at this time (Thursday) known.

The miners have not asked that the penal clause be stricken out. They have only asked that it be modified so as not to apply to mines now legally working, which would be compelled to shut down under the provision. Failing in this, they ask that the activity of the penal clause be suspended until the U. S. Commission is organized and ready to grant the licenses to mine required by the bill. The reason for this is that it may take a year or two for the Commission to formulate and adopt its general plans and be ready to issue commissions. Pending that time, all mines will have to close unless the clause referred to is modified. It should be remembered that the miners do not ask to have the modification apply to all mines in the State, but only to those which are working legally with restraining works, or where they are otherwise doing no damage. At the same time, it must be confessed there is a division of opinion among the miners as to the advantages of the bill as it stands.

Coal and Iron on the Pacific Coast.

The foundrymen and other iron manufacturers of this city have united in a petition to Congress (printed in another column) asking for the abolition of duty on coal, iron, iron ore, coke, scrap iron and scrap steel. The fuel used here in the melting and blast furnaces is all imported and pays 75 cents a ton duty; while over 90 per cent of the iron and steel scrap used has to be imported. Under these circumstances the iron industries of this city and coast cannot flourish, nor can they compete with Eastern establishments favorably. Of course, in matters of this kind, a tariff revision cannot be applied to one section of the country, but must be the same in all. For this reason, the petition will naturally meet with powerful opposition in the East, as the Pennsylvania "iron barons" would seriously object to any such step. However, it would seem as if such necessities as coal and iron should be procured as cheaply as possible. On this coast we are working

scarcely any iron deposits and depend largely on foreign coal.

The vessels which come here for wheat bring quantities of pig iron, but all the rest that is used comes across the continent. The tariff on one hand and the railroad freight on the other make the cost of the raw material excessive. This has been one of the factors in all cases where San Francisco machine-builders and contractors for iron or steel work had to bid against Eastern men in the same business, and it has always been a big draw-back to the local trader.

It will be seen that the largest firms in the city have signed this petition, including the Pacific Rolling Mills and Union Iron Works, which employ several thousand men. Could the articles mentioned be put on the free list, our manufacturing interests here would immediately feel the effect, and there would be more of them. This movement has nothing to do with politics, but is pure business. Many of the signers of the petition are prominent protectionists, but they feel that under present conditions the manufacturing industries of California do not have a fair chance.

Coast Industrial Notes.

THE starch factory at Petaluma is nearly completed and in a few weeks will be ready for operations.

THE Yolo Board of Supervisors has selected a site in Woodland as the location of the County High School. It is intended to begin at once the erection of a \$17,000 building.

A MEETING of the citizens of Fresno was held Tuesday to consider the Monterey and Fresno railroad project. Considerable interest was shown in the scheme, and \$20,000 of the \$75,000 asked by the projectors of the road was subscribed. A committee on subscription was appointed to solicit the remainder.

THE Southside Improvement club at a meeting this week decided to do all in its power to raise a subsidy of \$125,000 toward building the Metropolitan electric road to the ocean beach. The quarters at 640 Market street have been rented for the purpose of collecting this money, and Mr. Pope has promised that he will attend to the office.

THE Piedmont Cable Company is putting in another sharp curve at the corner of Fourteenth and Washington streets in order to run its electric cars down the latter street. A protest has been entered against this curve and the company has agreed to arrange its road so as to please the property-owners.

THE first solid train of California canned fruits ever shipped by rail to one dealer in this country left San Francisco on Wednesday for D. M. Steele & Co., Omaha, Neb. The shipment consisted of twenty-three cars, containing over 4000 tons. The train goes via Central and Union Pacific and will run through on special time by daylight.

THE Italian fishermen, who recently dissolved the union by which the sales of fish were restricted, and had commenced sales at competitive rates, have decided that there is no money in such business and the old scheme has been restored. The result has been very satisfactory, as the men who had been losing from \$15 to \$20 a week are now that much ahead.

THE House Naval Committee has decided to make no provision in the Naval Appropriation bill this year for new cruisers or battle ships. One new \$400,000 gunboat is the only vessel provided for. The total appropriation is \$2,000,000 less than last year. This is unfortunate for our local ship builders, for if there is only one vessel the East is apt to get it to build.

WORK has been commenced in Los Angeles on a large five-story brick building for the Oudahy Packing Co. buildings. When completed they will cover an acre of ground and will cost about \$150,000. The full capacity of the factory will be 500 hogs and 150 cattle per day, and when running in full force it will employ at least 200 men. It is estimated that the tributary territory south of Bakersfield now pays out annually for Eastern hog products nearly a million and a half dollars.

AN act to provide for the establishment and maintenance of a training-ship for the instruction of the boys of California in nautical matters has been recommended by the Chamber of Commerce for passage by the legislature. The act calls for the State of California to appropriate the sum of \$100,000 therefor, and the authorizing of the Governor to procure from the Government a ship of suitable size and tonnage for the accommodation of 230 boys.

AT a meeting of the Trustees of the town of San Rafael, held this week, bids were opened for an engine for the town pumping works. Considerable rivalry existed between the bidders, there being seven. Some bids were rejected, as they were not accompanied by a certified check, as required by the Trustees. After considerable wrangling the contract was awarded to A. L. Fish of San Francisco for \$15,000, he being the lowest bidder. Fish is the contractor who put in the new plant which has just been completed.

H. A. McCRAVEY, of the Lakeport *Avalanche*, Lake county, says: "We have been needing a railroad for a long time now, and I think we are about to get it. Three different companies have been figuring to run a road from either Pieta or Hopland, on the Donahue line, to Lakeport, via Highland Springs. The proposition has been for us as citizens to raise \$50,000 by subscriptions and they would build the road. The matter has been receiving our attention for some little time. We have got \$30,000 raised, and there is no doubt that we will secure the remainder. The road will be about 25 miles long and will cost in round figures about \$350,000 besides the subsidy. It will be an

electric road and will admirably suit the needs of the people. The line will go through Big Valley, one of the richest sections of northern California, a region of fine farms and orchards, and there will be much produce of this kind to carry out.

WORK on two of the tunnels between Santa Margarita and the town of San Luis Obispo is making good progress. The first tunnel south of Santa Margarita, which is the longest of the seven, being 36165 feet long, is now being bored at both ends. A day and a night force is at work and 430 feet of the tunnel is already completed. The work progresses at the rate of ten feet a day, so that it is calculated that it will be finished in 316 days from the time the first shovelful of dirt was moved. On the next tunnel only a day force is now at work.

CLOSELY following on the recommendation of San Pedro as a site for the Government harbor comes the news that the Southern Pacific Company will soon begin work on an important improvement on its San Pedro line. The long trestle which crosses the Wilmington slough, between the two towns of Wilmington and San Pedro, is to be replaced by a solid embankment. Work will be commenced at once at filling up the trestle with stone and soil, and will be continued until the pile work is supplanted by a more solid foundation for tracks. The growing traffic of that branch and the age of the timbers in the trestle call for substantial improvement.

REPRESENTATIVE CAMINETTI of California has introduced in Congress a resolution directing the Secretary of War to cause to be made, under the supervision of the Chief of Engineers of the United States army, examinations or surveys, or both, of the navigable waters of the river system tributary to the bay of San Francisco, with the view to permanent improvement for the purposes of commerce and navigation, by means of levees or otherwise, so as to obtain the following depth: At low water, nine-foot depth to the city of Stockton, three feet to Hill's Ferry, seven feet to the city of Sacramento, three feet to a point near Chico, 30 inches to McIntosh Landing, 20 inches to Red Bluff, 30 inches to the city of Marysville, and to report the result thereof to Congress on or before November 1, 1893, with complete plans and details of the same, together with estimates of the cost.

INDICATIONS point to the establishment of a new railroad through the Santa Clara valley, to be owned and operated by the San Francisco and Santa Cruz Railroad Company. The company was originally formed for the purpose of building a railroad between Ravenswood and Gilroy, one from San Jose to Alviso, and one from San Jose to Saratoga. The first named road will be operated under the name of the San Francisco and Santa Clara Railroad, and the last two under the name of the San Francisco and San Jose Transportation Company. It is intended to connect Ravenswood with San Francisco by steamers. One of the promoters of the new road says that the details have all been arranged and that work will commence in a short time. He adds that the necessary equipments of the road have been contracted for and that some of the material is now on hand. Part of the road is expected to be in running order on May 1st next.

SUPERINTENDENT RUTHERFORD of the California Cotton Mills at East Oakland gave some interesting facts about that industry last week before the Senate Committee on State Prisons, which is considering the bill to establish a cordage factory at Polson. The cotton mills never employed Chinese, and had, during the past eight years, paid out over a million dollars in wages. The company had put in very expensive machinery, and was largely engaged in the manufacture of twine, cotton and jute cordage. He supplied the hop growers with all their twine and the fishermen from San Diego to British Columbia with tackle and cordage. There was not room for another factory. He claimed that the factory proposed would be very expensive. The \$190,000 would be but a trifle of the whole cost. The cotton mills employed about 100 men and boys and 100 women and girls, paying laborers about \$1 a day, but to skilled help \$50 to \$90 per month, and the company had been declaring five per cent dividends.

THE report of E. C. Prieber, Viticultural Commissioner of Napa county, has just been issued from the State Printing Office. When the last census was taken, Napa county reported 18,299 acres in vines. The present report shows a decrease to 16,651½ acres. Of the 507 vineyards in the valley, 244 report phylloxera. The disease is now spread over 2246 acres. Whenever resistant vines have not been used, the death of the vines appears to be only a question of a short time. The reports of wine stock show that there are 5,000,000 gallons now in the valley. The commissioner stated that no remedy to prevent the spread of the disease had been discovered, and at only two of the entire number of vineyards visited was the disease being specially treated. As a rule, vineyardists have come to the conclusion that any special treatment is useless. The report states that some of the cellars are overstocked with wine of the vintage of four years ago, and prices are considerably below the figure desired.

THE Alaska Packing Association was incorporated this week with \$5,000,000 capital stock. The directors are E. B. Beck, E. B. Pond, Isaac Liebes, Chas. Hirsch, H. F. Fortman, Sidney M. Smith, Geo. W. Hume, H. A. Williams and S. B. Peterson. The company has paid out already \$3,000,000 for 27 Alaska salmon canneries and has \$2,000,000 left for sinking capital. The new company is to allow only such a catch each year as the market calls for. The canneries will therefore be run to that same purpose. Prices will remain just as they are, for the very good reason, if no other, that salmon are too plentiful to be a luxury. For the canning business the commodity must be one of general demand or else our business could not be made to pay. If prices were raised the commodity immediately becomes a luxury, and the demand would necessarily fall off. There is absolutely no profit in the business unless our goods can be placed on the market so that they can be purchased by everyone. When the market was overstocked during the past few years it did not make

a particle of difference in the prices. Warehouses and canneries, as well as stores, were packed. Salmon, in cans, keeps readily, and no sales were made under the regulation prices, hence every once in a while the canneries became silent and men were thrown out of employment. Now, they will run all the time, but will only furnish what the demand calls for. The demand is increasing yearly and last year when the canners combined under the form of a lease of all their institutions, the output was 685,000 cases, as against 347,000 for the year previous. The catch two years ago was just as large, however, as last year, and it is there that you can see the wanton loss of fish. The Sacramento River is about dead, so far as salmon is concerned. Two years ago the output from there was 235,000 cases, and only 5000 cases were obtained last year. That kind of business cannot possibly continue without eventually killing all the fish in the Columbia and Alaska waters as well.

AN interesting lecture on the subject of natural gas in the San Joaquin Valley was delivered Monday night to the members of the Academy of Sciences by W. L. Watts of the State Mining Bureau. Mr. Watts spoke of the way natural gas was discovered in the valley, and of its commercial benefit to the State. He also said that a series of experiments were made by the State Mining Bureau to determine the fuel value of the Stockton gas. Repeated experiments with gas from seven different wells showed that 1,000 cubic feet of gas had an average fuel value equal to that of 50 pounds of coke carrying 10 per cent. of ash. Mr. Watts also said that a review of the different wells which have been bored at Stockton shows that the deepest produce the most gas. One well that is nearly 3,000 feet deep produces 80,000 cubic feet of gas daily. Mr. Watts thought it would be very advisable that a deep experimental well be bored to ascertain the gas-yielding formations, and whether the water can be excluded by tightly casing the upper portion of the well.

THE officials of the Southern Pacific Co. are taking steps to convert from a narrow to a broad gauge the line known as the Santa Cruz division, which runs from this city to Santa Cruz. All freight shipped from stations on the road to points on broad-gauge roads, or out of the State, has to be transferred from the small cars to the large ones, and the business has grown so great that the rehandling has proved a nuisance. The officials deny that any change will take place for many years to come, but the fact remains that many preparations are now being made to lay a third rail in order that broad-gauge freight trains may be run over the road. Work of laying a third rail from Alameda to Los Gatos, at the foot of the Santa Cruz mountains, is being carried on and the officials expect to have broad-gauge trains running between these points by next fall, that they may take out the large fruit crop without rehandling it. None of the many tunnels on the road are wide enough to admit of the passage of broad-gauge cars, and experiment is about to be made to ascertain the cost of enlarging the narrow-gauge tunnels. Lumber and timbers are now on the ground at Rincon, a point two and a half miles north of Santa Cruz, where there is a short tunnel and which was chosen as the best place to learn the cost of remodeling tunnels.

A. HOGG, President of the Midway Lumber Company of Kansas city, Mo., who has been buying shingles in the Puget sound country, in speaking of the trade says: "You ask me why I go to Puget sound to buy my shingles and why California redwood could not be used in every way as well as Washington cedar? I will tell you. California redwood makes as good shingles as any of the woods which grow on the Puget sound, yet there is a difference of 20 cents a 1000 between shingles made of redwood and those from the cedar of the northwest. The lack of transportation is against the use of your redwood for the making of shingles. The freight rate on shingles from Portland and the Puget sound countries to the East is 55 cents per 100 pounds. The rate east from San Francisco is the same, but you must remember that redwood in any considerable quantity comes from Humboldt and Mendocino counties and it must be transported to San Francisco by water. This rate added to that of 55 cents per 100 makes the Washington shingle 20 cents cheaper than the one made from California redwood. When you extend your facilities of transportation in such a way as to bring your redwood under similar rates with those of the cedar from the Sound countries it will find a great demand and ready market in the East. California redwood makes one of the finest shingles in the world, and it seems a pity that so little of it is in the market.

THE condition of the market for canned salmon as described in the trade circular of the Cutting Packing Company is as follows: The market is devoid of any interest, stocks in first hands being exhausted and transactions confined to small parcels wanted in distributive trade. A vessel having been laid on here for New York at a nominal freight to avoid taking on ballast has had the effect of moving quite a line of Alaska fish from here to Atlantic points, but it was all sold prior to shipment and was only waiting some such favorable opportunity to secure cheap transportation. Preparations for the coming season's pack are being made and supplies being purchased for use, both at Columbia River and at Alaska points. It is expected that the high price for raw fish on the Columbia prevalent for several years past, will be maintained by the fishermen the present season, and the proposed combine among the canners will end as it commenced—"in talk." The Alaska canners have been more fortunate in arriving at an understanding, and while the majority of those interested have deemed it wise to act for common and mutual benefit, quite a number have preferred to retain their individual interests and manage their affairs as it seems best to them; so consumers need have no fear of their being any monopoly; and although no prices have yet been made on the Alaska product, some sales have been effected on whatever may be an opening price. Free engagements are reported of British Columbia brands and at good prices. Reports from all consuming markets indicate a satisfactory and healthy condition.

Borax.

Borax is a substance produced in the United States, only in California and Nevada. Immense quantities are taken from the fields which lie on the borders of these two States. By reason of the many useful purposes to which this salt has come to be applied, we have thought it worth while to compile and roughly classify some of these uses, taking them in the order of their seeming importance.

CURATIVE AND REMEDIAL.

Although the largest consumption of this salt is made by the preservers of meat, fish, etc., it finds its most beneficent uses as a purifying and curative agent. According to the United States Dispensatory, it is a mild refrigerant and diuretic, useful in diseases of the kidneys and other urinary organs, also calculus, a complaint due to an excess of uric acid. On the same authority, borax may be employed to great advantage as a gargle in cases of diphtheria and other ailments of the throat; also in colds, hoarseness, sore mouth or thrush, a peculiar soreness of the mouth, accompanied with dryness. For these latter troubles make a pint of strong sage tea; take one-half ounce alum, a lump of borax size of a large marble, pulverize these fine and put in the tea and sweeten well with honey; dose, tablespoonful for adult, teaspoonful for a child, to be taken after eating or drinking. For a throat gargle, make a strong solution of borax and common salt, mix with glycerine or honey; gargle thoroughly; it kills the deadly microbes, bacilli and the like. A bit of crystallized borax the size of a pea dissolved in the mouth relieves hoarseness and coughing and loosens the mucous gathering in the throat. For cold in the head and catarrh, snuff a pinch of the powdered salt up the nose. For epizooty in horses, place four ounces pulverized in the grain daily. For eczema, scrofula, ringworm and other cutaneous diseases, wash well with castile soap and then with a strong solution of borax and vaseline. Mixed with glycerine, it forms the best possible dressing for ulcers, also wounds, especially where there is proud flesh or gangrene. Borax is not to be used internally except by the advice of a physician. The bottle, tube, nipple or other implement used in the nursery should be washed in a hot solution of borax every time it is used.

IN THE HOUSEHOLD.

Powdered borax is an excellent insecticide; mixed with an equal quantity of gum camphor, it becomes more effective. It kills or drives away cockroaches, black beetles, ants, etc., scatter over the shelves or under the paper that covers them. It does not, like some other insecticides, endanger either human or other animal life. It should always be added to dishwater because of its detergent and purifying properties. Borax water should be boiled for 15 minutes every week in the coffee-pot to sweeten and cleanse it. It softens water hardened by the presence of lime or other substance. It is much better than soap or soda for washing glass and tinware, also painted or varnished wood, the coating on which soap, soda, and even ammonia, tend to remove.

LAUNDRY.

In the laundry this salt is a most valuable auxiliary not only because of its detergent properties but because it does not, like most other powerful detergents, injure the fabrics to which it is applied. On the contrary, it tends to soften and preserve them. The washerwomen of Holland and Belgium have long been noted for the excellence of their work, their linen being unrivaled for its softness and whiteness, a result due to a free use of borax in their lavatories, their practice being to add about $\frac{1}{4}$ of a pound of powdered borax to 5 gallons of water. This being a neutral salt does not injure the finest lace or other delicate fabric, which will not bear rubbing or being washed with soap or other of the caustic alkalis. In treating these the practice is to leave them in a weak solution of borax over night, then carefully rinse several times and press out the water without rubbing. In cleansing coarse fabrics this salt may be employed in connection with or as a substitute for soap. In washing blankets or other flannels put a tablespoonful of borax to a pail full of cold water; make a strong suds from good soap and throw both into the tub, rinse well in cold water, each time pressing or snapping out the water, then hang out to dry—do not wring. One teaspoonful powdered borax added to each quart of boiling starch increases the stiffness of articles to which it is applied, also imparts an additional glaze. The yolk of an egg, a little powdered borax and a teaspoonful of the spirits of camphor in half pint of tepid water takes the spots out of black goods. When red or white table linen is to be washed add borax to the water; when blue and white, sugar of lead. Always use a little borax in the bath; also in washing colored clothes, as soda has a bad effect on these.

TOILET.

In none of its minor uses does the employment of this salt serve a greater variety of desirable ends than in making the toilet. It is nature's best cosmetic. While it invigorates the skin it freshens and beautifies the complexion—for improving the latter nothing equals it. It also tends to purify the breath and preserve the teeth. For general toilet purposes, including shampoo, washing hands and face, cleaning comb and brush, etc., pour the refined into a bottle of warm water till no more will dissolve; pour off into another bottle and add half as much more water and shake well. If not clear let it stand till clarified, then pour off clear or filter through paper; can be used as a mouth wash, also to remove the odor of perspiration, etc.

For coarse, open pores on any part of the face 2 tablespoonfuls of borax dissolved in $\frac{1}{2}$ pint boiling water; add a little alcohol or cologne; wash frequently. For sunburn mix 6 grains borax and 1 ounce lime water with $\frac{1}{2}$ ounce of oil of jasmine and some oil of almonds. For freckles, 1 teaspoonful borax, 4 ounces lime juice and 2 tablespoonfuls of

candy sugar; mix well and add a little cologne water. For retaining the hair in curl dissolve 2 ounces borax, 1 dram gum arabic in 1 quart hot but not boiling water; add 3 tablespoonfuls strong spirits camphor; on retiring wet the hair with it and roll in twists or paper till morning. The unguent used by Sarah Bernhardt to keep the hands soft and white consists of equal parts lemon juice and glycerine with a little borax, with the triple extract of violets added.

AS A DENTIFRICE.

Four parts prepared chalk, four parts borax, two parts castile soap, a little pumice stone, all finely powdered and mixed and flavored with wintergreen, make a good and cheap dentifrice. The fancy preparations, though they cost a great deal more, do not make so good a tooth-powder as this, though most of them contain some borax.

FOR PRESERVING MEAT, FISH, ETC.

The large meatpackers and fishcannery employ borax by the carload for preserving their products, which, without injuring their healthfulness or their flavor, can, through its use, be kept good for an indefinite period. This salt possesses the peculiar and valuable property of destroying the organisms, both animal and vegetable, on which fermentation and putrefaction depend. A light sprinkling of this powder over meat will keep it good for some days. It is removed by pouring over it a little warm water. One part in a thousand will prevent milk souring for 24 hours—a quantity not injurious. Generally, however, this salt should be used only in accordance with a properly prepared formula. The extent to which the use of borax for curing meat has increased is shown by the fact that in 1883 the packers of Chicago, Kansas City and St. Louis employed for that purpose not more than 2000 pounds, whereas their consumption now exceeds 3,000,000 pounds.

MANUFACTURING AND METALLURGICAL USES.

In several of the economic industries this invaluable salt finds a place. The potters use it in enameling and glazing their wares; the calico printers as a mordant in drying; the plasterers in slacking lime, which it tends to harden and render fireproof; the hatters for making a varnish, which, boiled with shellac, gives stiffness to their fabrics. It is also used for manufacturing a soluble cream of tartar. Dissolved in water and mixed with linseed oil it makes a cheap paint. In connection with casein it can be substituted for gum. It is superior to alum for rendering cloth and like substances fireproof. It forms a valuable addition to all kinds of soap. It tends to the preservation of wood. From a mixture of boracic acid and milk an artificial ivory is made, well suited for billiard balls, combs, etc. Borax is much used in assaying and metallurgy, especially in the smelting of copper ores. The performer of strange and startling feats suffers no inconvenience from licking a bar of red-hot iron, if only be first take into his mouth a properly prepared solution of borax and alum. In view of its many and important uses, a supply of borax should be kept constantly on hand in families. Better be without many of those other articles usually deemed indispensable in the household, than without this salt, an adequate supply of which costs comparatively little.

The "Bally" Cam for Stamp Mills.

The "Bally" cam is an appliance now successfully working at Johannesburg, Transvaal, (Africa), on the quartz mills there. Chas. Raleigh & Co. (limited) have sent us circulars, from which we take the following:

Up to the present it has been the practice in millwork to build each five-stamp battery with all five cams either on the right ("right-hand" batteries) or on the left ("left-hand" batteries) of the stem-rod, consequently each stamp revolves in one and the same direction.

The immediate result of this "one-sided" arrangement is: 1st, a heavy side thrust on one cam-shaft bearing, causing excessive friction; 2d, the stamps fall to the one side of the dies, wearing them unevenly; 3d, the ore is caused to "silt" to one end of the mortar-box.

When a right-handed cam in motion engages a tappit, the stamp is thrust to the left (as far as the guide-block will permit), the cam and cam-shaft travel to the right, until the right-hand collar grinds hard up against its adjoining bearing. As the motion continues, and the cam lifts the stamp, the stem-rod travels sideways up the guide-block, and on falling (unless the guide-blocks are quite new) drops to one side of the die, and gradually wears the latter unevenly. The uneven die has then to be replaced, although only perhaps half or two-thirds worn, as it is past efficient duty, and liable to break the stem-rod. The result of the stamps continually revolving in the same direction is to "bank" or "silt" the ore to one end of the mortar-box, and effectually prevent the end stamp from doing its full duty. Thus it will be seen that a "one-sided lift" must necessarily cause a one-sided and unequal wear and strain over the whole of the battery, and result in an excessive expenditure on repairs of its wearing parts.

The patent "Bally" or balanced cam is introduced for the purpose of mitigating the evil effects resulting from a one-sided lift as exerted by the right or left-handed cam, and is simply a combination of the former and latter, each stamp being alternately lifted on its right and left-hand side, and revolved in these alternate opposite directions.

By arranging the order, there is always a right and left-hand cam engaged at the same time, their "thrusts" equalize each other, and the cam-shaft runs balanced between its bearings, the collars running free of the latter.

To gain this result six cams are used, having a total of only ten arms, there being four double-armed and two single-armed cams employed.

The double-armed cams are both right and left-handed, that is, they operate first on the right-hand side of one stamp, and then on the left-hand side of the adjoining stamp. The results of the use of this cam are claimed to be: less friction, level wearing of dies, greater crushing efficiency, higher speed, greater rigidity and less danger in cleaning up.

Free Coal and Iron Wanted on the Pacific Coast.

A mammoth petition to Congress, praying for the boon of free coal, iron ore, coke, pig iron, etc., and signed by 120 of the heaviest manufacturing firms of San Francisco, is on its way to Washington. Many of the signers are Republicans in politics. It is a nonpartisan commercial cry of the Pacific Coast. The document is as follows:

To the Senators and Representatives in Congress of the Pacific Coast States and Territories: We, the undersigned, members of all political parties, engaged on this Coast in iron and steel manufacture, respectfully submit the following facts:

First—That these industries are now in a deplorable condition.

Second—That owing to the quality of Coast coals, we are obliged to import the fuel used in melting and blast furnaces, which imposes on us a special tax of 75 cents per ton, and does not benefit even the native coal producers.

Third—That owing to the insufficient local supply, we are forced to import 90 per cent of the iron and steel scrap used in our business, which, on account of the cost of transportation, could not be had from any native source.

And finally, believing that were the duties removed on the materials named hereafter, a marked impulse would be given to the manufacturing industries on this Coast without detriment to any other established interest or section of the country, we request that in the revision of our tariff, which now seems imminent, you urge the insertion of the following provisions:

That iron ore, coal, coke, pig iron, scrap iron and scrap steel shall be placed on the free list.

San Francisco Iron Works.
D. D. Wass, iron fence and wire works.
M. A. Graham, Oriental Gas-Engine Works.

THE Arcata Union referring to the oil wells in the Garberville section of Humboldt county says it is informed by an oil expert that operations on the oil well near Garberville have ceased, and the casing was being removed from the well, after a depth of more than 2,400 feet had been reached. He gave it as his decided opinion that there was no prospect of finding oil in paying quantities on the formation where the well was being sunk, as due consideration had not been given to the geological formation of the location. He is of the opinion, however, that oil may be struck by sinking a well farther south than the present location, and is ready and willing to try the experiment, either at his own expense, or in connection with the company now formed, if the use of the machinery owned by the company can be had.

The Stewart Mining Bill.

Full Text of a Measure Important to Miners.

In the Senate of the United States, Dec. 10, 1891, Mr. Stewart introduced the following bill, which was read twice and referred to the Committee on Mines and Mining:

February 2, 1892, it was reported by Mr. Stewart with amendments, viz.: Omit the parts in SMALL CAPS and insert the parts printed in italics.

A Bill to Amend Chapter Six of Title Thirty-two of the Revised Statutes Relating to Mineral Lands and Mining Resources.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section twenty-three hundred and twenty-four of the Revised Statutes be amended to read:

"SECTION 2324. The miners of each mining district may make regulations, not in conflict with the laws of the United States or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording the amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground by posts or monuments so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located as will identify the claim. On each lode claim located after the tenth day of May, eighteen hundred and seventy-two, and until payment of the purchase-money and a certificate of entry has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year. On all lode claims located prior to the tenth day of May, eighteen hundred and seventy-two, ten dollars' worth of labor shall be performed or improvements made during each year for each one hundred feet in length along the vein until payment of the purchase-money and a certificate of entry has been issued therefor; and for each twenty acres of placer claims, and for each subdivision thereof less than twenty acres, ten dollars' worth of labor shall be performed or improvements made during each year until payment of the purchase-money and a certificate of entry shall be issued therefor. But where several adjoining lode claims, not exceeding five, are owned or held by the same person, association or corporation, and the sum of five hundred dollars or more is expended in any one year in good faith for the development of all of the claims so owned or held, not exceeding five, there shall be no requirement for separate labor or improvements to be performed or made on the several claims so owned or held during such year. The year within which the annual labor or improvements required to be performed or made by this section shall commence at twelve o'clock meridian on the first day of October of each year; *Provided*, That upon claims located previous to the first day of March in any year the annual labor or improvements shall be performed or made on such claim for that year prior to twelve o'clock meridian on the first day of October next succeeding, and upon claims located after the last day of February and prior to twelve o'clock meridian of the first day of October in any year, the annual labor or improvements required shall be performed or made within one year from twelve o'clock meridian of the first day of the succeeding October: *And provided further*, That only one-half of the annual labor or improvements required by this act shall be necessary to be performed or made prior to twelve o'clock meridian of the first day of October, in the year eighteen hundred and ninety-one, on claims upon which the annual labor or improvements were performed or made in the year eighteen hundred and ninety-one; but after the first day of October, in the year eighteen hundred and ninety-one, the full amount of labor or improvements required by this act shall be performed or made upon such claims as to all other cases during each year prior to twelve o'clock meridian of the first day of October. In case the first day of October falls on Sunday or any holiday, the following secular day shall be construed as the first day of October within the meaning of this act. When the labor required by this act shall have been performed or the improvements made, an affidavit may be filed within thirty days after the time limited for performing such labor or making such improvements with the recorder of deeds of the county in which the claim or mine is situated, particularly describing the labor performed and improvements made, and the value thereof, which affidavit shall be prima facie evidence of the facts therein stated. And upon a failure to comply with the conditions of this act in the performance of labor or making of improvements, the claim or mine upon which such failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made: *Provided*, That the original locators, their heirs, assigns or legal representatives do not resume work upon the claim after such failure and before such relocation, and continue the same with reasonable diligence until the required amount of labor shall have been performed or improvements made; but no relocation of a claim by a person who has already located such claim and failed to comply with the conditions of this act to performing work or making improvements shall be valid prior to such resumption and continuance of work upon such claim. Upon the failure of any one of several coowners to contribute his proportion of the expenditures required hereby, the coowners who have performed the labor or made the improvement may, at the expiration of the year, give such delinquent coowner personal notice in writing or notice by publication in the newspaper published nearest the claim for at least once a week for ninety days, and if at the expiration of ninety days after such notice in writing or by publication such delinquent shall fail or refuse to contribute his proportion of the expenditure required by this section, his interest in the claim shall become the property of his coowners who have made the required expenditures. A copy of such notice, together with an affidavit showing personal service or publication, as the case may be, of such notice, when filed and recorded with the recorder of deeds of the county in which such mining claim is situated, shall be evidence of the acquisition of title of such coowners. Where a person or company has or may run a tunnel for the purpose and with the intent to good faith of developing a lode or lodes owned by said person or company, the money so expended in running said tunnel shall be taken and considered as expended on said lode or lodes: *Provided further*, That said lode claim or claims shall be distinctly marked on the surface as provided in this act."

SEC. 2. That section twenty-three hundred and twenty-five of the Revised Statutes be so amended as to read:

"SEC. 2325. A patent for any land claimed and located for valuable deposits may be obtained in the following manner: Any person, association or corporation authorized to locate a claim under this chapter, having claimed and located a piece of land for such purposes, who has, or have, complied with the terms of this chapter, may file in the proper land office an application for a patent, under oath, showing such compliance, together with a plat and field notes of the claim or claims in common, made by or under the direction of the United States surveyor-general, showing accurately the boundaries of the claim or claims, which shall be distinctly marked by monuments on the ground, and shall post a copy of such plat, together with a notice of such application for a patent, in a conspicuous place on the land embraced in such plat previous to the filing of the application for a patent, and shall file an affidavit of at least one person that such plat and notice have been duly posted, and shall also file a copy of the notice in such land office, and shall thereupon be entitled to a patent for the land in the manner following: The register of the land office, upon the filing of such application, plat, field notes, notices and affidavits, shall publish a notice that such application has been made, for the period of sixty days, in a newspaper to be by him designated as published nearest to such claim; and he shall also post such notice in his office for the same period. The claimant at the time of filing this application, or at any time thereafter within the sixty days of publication, shall file with the register a certificate of the United

States surveyor-general that five hundred dollars' worth of labor has been expended or improvements made upon the claim by himself or grantors; that the plat is correct with such further description by such reference to natural objects or permanent monuments as shall identify the claim, and furnish an accurate description, to be incorporated in the patent. At the expiration of sixty days of publication the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during such period of publication. If no adverse claim shall have been filed with the register and receiver of the proper land office at the expiration of the sixty days' publication it shall be assumed that the applicant is entitled to a patent, and that no adverse claim exists, and upon the payment to the proper officer of five dollars per acre he shall receive a certificate of entry; and thereafter no objection from third parties to the issuance of a patent shall be heard except it be shown that the applicant has failed to comply with the terms of this chapter. But no more than three thousand feet in length along the vein OR on claims located prior to the tenth day of May, eighteen hundred and seventy-two, and not more than the extent of fifteen hundred feet in length by six hundred feet in width located after said date, shall be included in the same application for a patent, and not more than forty acres of placer or petroleum ground or land that is chiefly valuable for building stone shall be included in the same application for a patent: *Provided*, That when fractional claims are located or sought to be patented between other existing claims the end lines may be made to conform to the lines of such adjoining claims."

SEC. 3. That section twenty-three hundred and thirty-four of the Revised Statutes be amended by adding thereto the following:

"And the surveyors appointed under the provisions of this section shall have power to administer oaths to their assistants."

SEC. 4. That section twenty-three hundred and thirty-five of the Revised Statutes be amended to read:

"SEC. 2335. All affidavits required to be made under this chapter may be verified before any officer authorized to administer oaths in any State or Territory of the United States or in the District of Columbia having an official seal, and all testimony and proofs may be taken before any such officer, and when duly certified by the officer taking the same, attested by his seal of office, shall have the same force and effect as if taken before the register and receiver of the land office. In cases of contest as to the mineral or agricultural character of land, the testimony and proofs may be taken, under such regulations and notice as the Commissioner of the General Land Office may prescribe: *Provided*, That the presence of rock in place bearing gold, silver, cinnabar, petroleum, or other valuable METAL mineral, shall be regarded as prima facie evidence that the land containing the same is mineral in character; *And provided further*, That in investigating the character of land with a view to ascertain whether it is more valuable for mineral than agriculture, evidence may be taken of the mineral discovered or developed adjacent to such land."

SEC. 5. That section twenty-three hundred and thirty-seven of the Revised Statutes be amended so as to read:

"SEC. 2337. Where nonmineral land not included in a lode claim is used or occupied, or is intended in good faith to be used or occupied by the proprietor of such vein or lode claim for mining or milling purposes, such nonmineral surface ground may be embraced and included in an application for a patent for such vein or lode claim, and the same may be patented therewith or separately, subject to the same preliminary requirements as to survey and notice as are applicable to vein or lode claims; but no location hereafter made of such nonmineral land shall exceed ten acres, and payment for same must be made at the same rate as fixed by this chapter for the superficies of the lode claim. The owner of a quartz-mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill-site as provided in this section."

S. 54—2.

SEC. 6. Amend section twenty-three hundred and thirty-eight of the Revised Statutes so as to read:

"SEC. 2338. As a condition of sale each patent shall reserve the right of way through or over any mining claims for roads, ditches, canals, cuts, tunnels and other easements, for the purpose of working OTHER mines and for agricultural purposes: *Provided*, that any damages occasioned thereby shall be assessed and paid in the manner provided by the laws of the State or Territory in which such mine is situated for assessments and payments for land taken for public use under the right of eminent domain. And the rights and easements heretofore reserved under the provisions of this section (twenty-three hundred and thirty-eight of the Revised Statutes) in patents heretofore issued shall be regulated and made available as heretofore prescribed."

SEC. 7. That town-site entries may be made by incorporated towns and cities on the mineral lands of the United States, but no title shall be acquired by such towns or cities to any vein of gold, silver, cinnabar, copper, or lead, or to any valid mining claim or possession held under existing law. When mineral claims are possessed within the limits of an incorporated town or city, and such possession is recognized by local authority or by the laws of the United States, the title to town lots shall be subject to such recognized possession and the necessary use thereof, and when entry has been made or patent issued for such town-sites to such incorporated town or city, the possessor of such mineral vein may enter and receive patent for such mineral vein and surface ground recognized by the local laws and statutes of the United States not held or possessed adversely to the claimant for such mineral vein by other than the said city or town, or when it shall appear that the claimant otherwise entitled to such mineral vein has acquired title to such surface ground from the said city and town: *Provided*, That no entry shall be made by such mineral-vein claimant for surface ground where the owner or occupier of the surface ground shall have had possession of the same before the inception of the title of the mineral-vein applicant."

COLLIERY DISASTERS.—An English paper states that although the year 1892 cannot be said to have been an improvement on the preceding one with respect to colliery explosions of a fatal character, it contrasts favorably with that of 1890, when 290 persons were killed. The fatalities in 1891 reached only 58, whilst in 1892 they amount to 126. The year's record is largely made up of the victims who perished at the Park Slip colliery in August last, when about 116 men perished, leaving 58 widows, 152 orphans, and 12 dependent relatives on an insufficient fund. With one exception, when two persons perished, the rest were single fatalities. It may be stated that since 1866, which was the worst fatal year on record, the number of lives lost by explosions have decreased. In the year named, 364 lives were lost at the Oaks colliery, near Barnsley, which swelled the grim record. The lowest year was 1884, when only 51 persons lost their lives by explosions in collieries.

It is generally supposed that no miller or any one connected with a flour-mill would ship flour in a car whose floor or sides were saturated with kerosene oil, but they do it frequently. The same person does not often repeat the action, but most every one shipping flour has to stand the expense of this experiment at least once. A Toronto baker recently had an expensive experience with flour that had absorbed enough of the odor of oil in transit to spoil it. The flour seemed to be all right, but the oven smelled strongly of oil when the first batch of bread was being baked. The bread was sold, but not eaten, and the flour was paid for by the shipper. Flour absorbs odors very

readily, and should not be placed in a small, musty room or near oil, onions or rotten produce of any kind.—Miller.

Ancient Gravels of Siskiyou County.

SAN FRANCISCO, Feb. 3, 1893.

TO THE EDITOR:—The "ancient blue channel" that extends through Siskiyou county from north to south, until obscured beneath the lava flows of Mt. Shasta is not unlike, in geological age and character of gravel, the "great blue lead of the Sierras."

This ancient river, in the writer's judgment, belongs to the Pliocene epoch, as is distinctly manifest by the fossil flora and fauna found in its deposits. Our leading geologists have, after scientific research, established the plausible theory that the age of these prehistoric streams belong to the Pliocene epoch of the Tertiary period. The time of their flowing activity has been so remote, however, that geologists can but establish reasonable theories and not positive facts.

The existence of this ancient stream in Siskiyou was not discovered until recently, owing no doubt to its submerged condition and the presence of an overlying stratum of sandstone. In the Cottonwood district, near the town of Henley, the channel has been exploited to some extent and the gravel found to be auriferous. Near Yreka a limited amount of development has been done upon it by means of shafts, but owing to the hard, cemented character of the gravel which necessitated heavy expenditures, the work was temporarily discontinued.

The geological features that distinguish the "great blue" of the Sierras in the various character of its stratum materials, namely, the heavy overlying cappings of volcanic ashes and basalt, are mostly absent from the channels of Siskiyou.

In the central mining counties the presence of these deep lava flows, some of which reach to a depth of nearly one thousand feet, makes it extremely difficult to exploit for the channels. The absence of the volcanic capping in this county, and in most sections the uncemented character of the bottom gravel, admit of a comparatively light expense in the exploitation and operation of the deposits.

There are in the county two distinct ancient river systems—first, the blue lead of the Pliocene period above referred to; the other a red gravel channel which extends in a northwesterly direction toward the present flowing Klamath river.

This latter lead is unlike the "ancient blue" both in character of channel-filling and topographical environments. On account of the absence of fossiliferous remains and other Tertiary evidences, there is reason to believe that its depositions occurred during a comparatively recent period. The primitive and natural configuration of the region through which the channel extends has, from recent geological causes, namely, by aqueous and dynamical forces, been decidedly changed. Heavy mountain displacements, torrential, transversing streams and glacial flows, have in many places so effectively disfigured the channel that it requires the most diligent research to correctly locate its original course.

These geological disturbances are confined principally to a section of the channel about 12 miles in length in the granitic formation between the headwaters of Scott river (near the south end and apparent source of this ancient stream) and Mill creek, near the town of Etna. Northwesterly from Etna the geological structure of the mountains changes to a metamorphic slate formation of a less disturbed condition. The channel extends along northwesterly, skirting the western side of Scott and Quartz valleys, hugging closely the base of the Salmon mountains, which rise abruptly upward to an altitude of 8000 feet.

It is followed with little difficulty for a distance of 20 miles, to where Scott river (a modern stream) has crossed and recrossed it to such an extent that it is almost entirely swept away and its auriferous deposit distributed along the bed of the present river.

The character of the "channel material" is a red colored auriferous gravel, consisting of a variety of boulders, pebbles, and sand eroded from the granite, syenite, serpentine, schists and slate formations. The sources of this "ancient river" occurred far up in the Scott mountain range. The supplying agencies from which it derived its origin were the higher ancient channels of Fox creek and the south fork of Scott river, both famous as rich gold-bearing streams.

Considerable adverse opinion prevails regarding its origin, many maintaining that it is a continuation of some ancient river having its sources in Trinity county. The practicability of the latter theory is an absolute impossibility. The topographical features of the mountain range that divides the two counties are such that at no period could any extinct or existing stream drain from Trinity to Siskiyou.

I am emphatically assured by personal investigations thoroughly made that its sources occurred no farther south than the south fork of Scott river.

In Quartz valley, at the "New Pinnery," a Stockton company is energetically operating a portion of the channel with remunerative results. At the "Old Pinnery," adjoining the New Pinnery, is situated the Deming property. Operations are conducted at this mine under the hydraulic process. The working seasons are comparatively short and the water supply limited. Notwithstanding this fact, the property yields annually very handsome returns.

At the extreme north end of the channel at Scott river is located the Red Point mines, the property of a San Francisco company. They are at present engaged in making preparations to develop the channel upon an extensive scale. This property consists of about 160 acres. Some prospecting work has already been done by the company and very rich gravel encountered.

The "breaks" or "overflows" deposited from the channel upon the flats along its course have been profitably worked in early days and give strong evidence that the bed of the ancient stream is highly auriferous.

FRANK HENRY HALL.

Educated Engineers and Amateur Experts.

TO THE EDITOR:—I had no idea that I was going to bring down on my devoted head such crushing rejoinders as those of your correspondents "Morton" and "Amador," as a consequence of an expression of my views on the subject of exaggerated mining reports, and the employment of amateur experts instead of educated engineers.

The burden of the two articles referred to is, that the educated engineer is at best a humbug, and a chronic blunderer, and instances are quoted as examples of their mistakes, in support of the argument.

I did not claim in my remarks that they were infallible, but simply that, being educated to the business, they ought to be more competent than the ordinary miner, who gains his knowledge and experience from swinging the pick, something the educated mining engineer has presumably had some practical experience in as well, as a part of his education. But be that as it may, I would like to hear from Morton, also Amador, as to the fact whether the practical man, that he holds up as superior to the scientific engineer, is always correct in his judgment on a mine, and whether he is not prone to make mistakes as often as the other man? Is he always correct?

If I had signed my article "Experience," instead of "Mining Sharp," it would have been more appropriate, as what I know about mines has been more the result of dealing in them than practical experience, and I make no claim to be competent to expert a mine. But I have been connected with mines from the opening of the Comstock, as owner, promoter, capitalist, superintendent, director, president and vender, at home and abroad—in fact, everything above ground that pertains to mines, and mining as a business—for 30 years, in the course of which period I have seen a good many things that have assisted me in forming my opinions of the practical and the scientific mining expert.

At one time I became imbued with the popular idea that the scientific man was a humbug, and I switched off to the practical underground toiler with a pick. My experience was not a happy one, and after spending more money in gaining it than I care to admit, I came to the conclusion that, while the miner often had most excellent judgment on the work immediately under his eye, it was of very little value beyond. I have never underrated the judgment of the practical miner in his particular line, but, as I say, my experience is, that something more is necessary than such superficial knowledge, and it is the business of the educated engineer to supply that want, and one that cannot be not the sort of a man that should set himself up as an expert.

It is a favorite theme to quote such men as Mackay, Head, Fair and Hearst as men who, from practical experience, seldom failed in their judgment of a mine. I happen to know that nearly all of them have made mistakes, and have had their losses like the rest of us, and, moreover, the most they know about mines has been gained quite as much since either of them has swung a pick as they ever knew before, and this has been gained by chewing the string of the pudding.

Senator Hearst and myself were closely associated in mining business in early days, and he often, when we were considering the question of the examination of a property and I urged that he should make the experting himself, was wont to say, "If it was all my own money that was at stake I would not mind, but I had rather pay my share and get a competent man." I would say, "You are a practical miner, and should be perfectly competent." His reply was, on one occasion, I remember, "There is a d—n sight about this mining business that we fellows don't know." The great secret of his subsequent success was what is really the only method of succeeding, and that is, to have the capital to open and develop promising prospects, and if one in five turns out well, it more than pays for all the others.

There is not probably any set of men that have paid more money to scientific, educated experts than these very men who are practical miners themselves. They are a good deal like doctors, who, when they get sick, having no faith in their own skill and ability, call in another practitioner. I admit that there is a great deal in both Morton's and Amador's arguments worth commendation, very sensible and truthful, but it strikes me they are rather sweeping in their condemnation of scientific engineers and must lament the stupidity and want of intelligence that has not yet discovered that the practical miner and superintendent is the only reliable and competent man to examine a mine, report on it as it is, or should be, and of course they never make mistakes.

I have a few pigeon-holes full of such literature that I get out at times when I want to read romances, and Jules Verne fails to come up to the standard; and as each has a note of how much I paid for it, I figure sometimes the many \$20 pieces they cost. I let my imagination run riot and guess what a big fortune I would have had if the gentlemen who made the reports had shown a little more scientific experience, and a little less of the practical. Some of these reports I have indorsed: "The report of truthful Jeems on the 'Bob-Tailed Nag' mine, with all its dips, spurs and angles, proving on further inspection to have nary a dip; nary a spur; nary an angle."

If a mining expert is to be judged by the mistakes he makes, why not the practical man's work also? If Morton or Amador would like to gather statistics on this question, I think I could come in with an armful of evidence that the practical expert does sometimes put his foot in it.

I do not feel myself competent to argue with either of the gentlemen, who I can't help thinking indulge somewhat in scientific terms and wise conclusions themselves, notwithstanding their professed contempt for anything of that sort; for I, as I explained, am only the man that has paid for the whistle, and am only blowing on it a little just to pass an idle hour. I shall leave it to some real, genuine, "educated" engineer to answer my two friends up country, who, at any rate, should feel under obligations to me for giving them the opportunity for getting their guns on the book-learned fellows, and giving them particular fits, as it

were; and if it is something they have had on their minds for some time, it will be a great relief, doubtless. Even more from the same source would, I do not doubt, be very acceptable to the MINING AND SCIENTIFIC PRESS, which, it is well understood, gives both sides a fair showing. I warn, however, both gentlemen that I shall hand over the fight to a competitor more worthy of their steel. I shall call to my aid one of those scientific sharps; then look out for yourselves, gentlemen.

"MINING SHARP."

The Woods of Washington and Oregon.

Following are the principal woods found in the different counties of Washington, from returns made to the *Lumberman*:

Asotin—Pine, fir, tamarack, alder.
Chehalis—Fir, spruce, cedar, Alaska pine, alder, maple, ash, larch.
Clallam—Fir, spruce, cedar, Alaska pine, alder, maple, ash, yew, Alaska cedar, oak.
Clarke—Fir, spruce, cedar, Alaska pine, larch.
Columbia—Pine, fir, alder, tamarack.
Cowlitz—Fir, cedar, Alaska pine, ash, maple, alder, larch, oak.
Douglas—Pine, fir, tamarack.
Garfield—Pine, fir, tamarack, alder.
Island—Fir, cedar, spruce, Alaska pine, maple, alder, cottonwood, ash, yew, oak.
Jefferson—Fir, cedar, spruce, Alaska pine, maple, alder, cottonwood, ash, yew, Alaska cedar.
King—Fir, cedar, Alaska pine, spruce, cottonwood, maple, alder, Alaska cedar, larch.
Kitsap—Fir, cedar, Alaska pine, spruce, alder, maple.
Kittitas—Fir, pine, cedar, larch, Alaska cedar.
Klickitat—Fir, pine, cedar.
Lewis—Fir, cedar, Alaska pine, ash, maple, oak, alder, larch, willow.
Lincoln—Pine, fir, tamarack.
Mason—Fir, cedar, Alaska pine, spruce, maple, alder, ash, cottonwood.
Okanogan—Fir, pine, tamarack, larch, Alaska cedar.
Pacific—Fir, Alaska pine, spruce, cedar, maple, alder, cottonwood, ash.
Pierce—Fir, cedar, Alaska pine, spruce, alder, cottonwood, ash, maple, Alaska cedar, larch.
San Juan—Fir, cedar, spruce, alder, maple, oak, yew.
Skagit—Fir, cedar, spruce, Alaska pine, white pine, larch, maple, alder.
Skamania—Fir, larch, pine, cedar.
Snohomish—Fir, cedar, Alaska pine, spruce, cottonwood, alder, maple, larch.
Spokane—Fir, pine, cedar, spruce, tamarack.
Stevens—Pine, fir, tamarack, spruce, cedar.
Thurston—Fir, cedar, Alaska pine, spruce, maple, alder, ash, cottonwood.
Wahkiakum—Fir, spruce, cedar, Alaska pine, larch, maple, alder.
Walla Walla—Pine, fir, alder, tamarack.
Whatcom—Fir, spruce, cedar, Alaska pine, maple, alder, larch.
Whitman—Pine, fir, cedar, spruce.
Yakima—Fir, pine, cedar.

It will be noticed that some of the woods mentioned as existing in the State are not given in the list by counties. The reason for this is that these woods are not found in very large quantities in any one place, but are scattered among other timber, some throughout several counties and others only in rather remote places. The woods mentioned in the county list comprise about all that are found in the State in large bodies.

Following are the principal woods growing in the counties of Oregon:

Baker—Pine, fir, tamarack, juniper.
Benton—Fir, pine, spruce, cedar, Alaska pine.
Crook—Fir, bull pine, cedar, sugar pine, yellow pine, juniper, mountain mahogany.
Clatsop—Fir, cedar, spruce, Alaska pine, cottonwood.
Columbia—Fir, spruce, cedar, oak, alder, maple.
Clackamas—Yellow fir, cedar, larch, pine, Alaska pine, ash.
Coos—Fir, spruce, white cedar, Alaska pine, maple, myrtle, ash, red cedar, oak.
Curry—Fir, yellow pine, sugar pine, oak, white cedar, red cedar, Alaska pine, spruce, maple, myrtle, ash.
Douglas—Fir, spruce, Alaska pine, red cedar, white cedar, oak, sugar pine, yellow pine, maple, myrtle, ash, cottonwood, alder.
Gilliam—Pine, fir, tamarack.
Grant—Yellow pine, fir, tamarack, bull pine.
Harvey—Bull pine, fir, tamarack, yellow pine.
Jackson—Yellow pine, bull pine, sugar pine, yellow fir, red fir, white fir, red cedar.
Josephine—Sugar pine, yellow pine, fir, spruce, Alaska pine, red cedar, white cedar, oak, cottonwood, myrtle, ash.
Lave—Red fir, yellow fir, red cedar, white cedar, Alaska pine, yew, maple, alder, balm, larch.
Linn—Fir, Alaska pine, cedar, larch, yew, alder, maple.
Malheur—Yellow pine, bull pine, fir, tamarack.
Marion—Fir, cedar, pine, Alaska pine, larch, oak.
Morrow—Yellow pine, fir, tamarack.
Multnomah—Fir, cedar, spruce, pine, Alaska pine, larch, alder, maple.
Polk—Fir, pine, spruce, cedar, Alaska pine, larch, oak.
Sherman—Fir, pine, tamarack.
Tillamook—Fir, spruce, pine, cedar, Alaska pine.
Umatilla—Pine, fir, tamarack.
Union—Yellow pine, bull pine, fir, tamarack.
Wallowa—Pine, fir, tamarack.
Wasco—Yellow pine, sugar pine, bull pine, fir, cedar, tamarack, juniper, mountain mahogany.
Washington—Fir, cedar, pine, Alaska pine, larch, oak, ash.
Yamhill—Fir, cedar, pine, Alaska pine, maple, alder, larch.

Notes on Palms.

Nothing in the whole range of vegetation so impresses the traveler from less-favored climes than the presence of lofty palms. At the residence of Mr. Kinton Stevens, of Montecito, Santa Barbara county, can be seen a pair of *Cocos plumosa* over 20 feet high, with well-defined trunk, less than 11 years old. In the same gardens can be seen thrifty specimens of *Seaforthia elegans* and *Jubaea spectabilis*, the "Coquito," or little coconut of Chili, the latter a very hardy palm; besides these, a good collection of fan-leaved palms, including "Sabal palmetto," of Florida. At the residence of Mr. Sheffield in Santa Barbara, can be seen a fine *Seaforthia*, which has already produced fertile seeds. In many other Santa Barbara gardens, smaller specimens of *Seaforthia* are growing, showing the appreciation of the Santa Barbara people for fine plants.

In Los Angeles the list is much smaller. At the home of Mr. E. Germain flourishes a thrifty plant of *Kentia Forsteriana*. This plant has been in the open three winters and is a model of health and beauty. Few species can surpass *Kentia Forsteriana*; it ultimately attains a height of 40 feet; indigenous in Lord Howes island. At Mr. H. Jevne's place a smaller example of the same species seems well established. Near Rosedale cemetery, in a private garden, a nice young specimen of *Cocos plumosa* occurs; out several seasons. At Mr. Forester's place, on Seventh street, and at Mr. Decler's place, on Sand street, are also good plants of *Seaforthia elegans*, out several years in the open ground; while at Coronado Beach, beautiful plants of *Areca Bauerii*, *Kentia Forsteriana*, *Seaforthia elegans* and *Cocos plumosa* can be seen.

There yet remains a number of good palms to be introduced to open-air cultivation, notably the following: *Kentia Belmoreana*, *K. Cantherburyana*, *K. Sapida*, *Areca Bauerii*, *Cocos flexuosa*, *C. Australis*, *C. coronata*, *C. Yalae* and *C. Romanzoffiana*, *Ceroxylon andicola*, *Caryota Urens* and *Ptychosperma Alexandria*, all of varying degrees of hardiness. At some particularly sheltered and warm places along the foothills, it is not improbable that *Oreodoxa regia* would flourish. The writer noted the experiment of a plant of this species tried in this city, which endured two winters, but the heavy soil during the third winter, owing to unusually heavy rains, became so cold and water-logged that the roots decayed and the plant perished. These considerations should always weigh in the attempt to cultivate new species of doubtful hardiness. Many a tropical plant will flourish and endure slight frost if not too frequent, if the soil be comparatively light and well-drained; while in a quite frostless location, heavy soil may become so charged with moisture that decay of the roots takes place, and the plant either languishes or dies outright.

It is not intended that the foregoing remarks are more than a glance at the possibilities of new introductions. We know comparatively little of the Andean palms of Bolivia, or the remoter Alpine regions of Venezuela, while Paraguay is almost a botanical terra incognita. Count Castelman, during his great Brazilian expedition, records having seen many palms on the confines of Paraguay, few of which anything is known. Spruce, in his valuable essay on the palms of the Amazons, alludes to several genera and species as occurring at considerable altitudes. *Iriartea ventricosa* and *I. exorrhiza* ascend the Andes to 5000 feet. According to Humboldt, *Ceroxylon andicola*, the famous wax palm of Columbia, was found growing to the Cordilleras, near the pass of Quindiu, between Ibague and Cartago, at from 7900 to 10,000 feet, in company with *Podocarpus* trees and *Quercus Granatensis*, not very far from the snow line.

From the temperate mountain regions of sub-tropical Mexico are known, among others, *Chamaedorea colorata* and *Copernicia pumosa* (the latter a fan-leaved palm), at elevations of from 7000 to 8000 feet. In the garden of the writer, *Chamaedorea Desmonoides* seems quite hardy. Some of the Mexican *Acrocomias* and *Astrocaryums* (splendid spinescent palms) would undoubtedly flourish in favorable places here. In Ceylon, *Oncosperma fasciculatum*, a slender-stemmed, prickly palm, of great elegance, occurs as high as 5000 feet, while *Copernicia cerifera*, the Brazilian wax palm, extends into Argentina, and would likely flourish here. Enough has been said, however, to indicate in some degree the possibility of adding many fine palms to cultivation here.

It should not be inferred that the fan-leaved section of palms is much less beautiful in all species than those of the former group. Indeed, a few species rival and some excel the pinnate palms in magnificence, and no paper would be in any degree complete without reference to them. Commencing with *Washingtonia filifera*, which is abundantly represented, we have, in lesser numbers, *Chamaerops excelsa* and *C. humilis*, picturesque, but stiff and ungraceful palms. Not quite so common is *Corypha Australis*, a fine Australian palm. Still rarer is *Lantania Borbonica*, a fine-fruited specimen of which can be seen at Mr. Hancock Johnson's place in East Los Angeles. There are two other fine palms rarely seen, and yet their native habitat is less than 400 miles distant. *Erythea edulis*, from Guadalupe island, off the coast of Lower California, and *E. armata*, occurring in deep canyons just below the State line in Lower California. They are both quite hardy and make splendid plants as they attain size. The former has rich, dark green leaves, much darker than *Washingtonia*, and without the filaments so characteristic of this species, while the foliage of *E. armata* is an ashy blue, and one of the most distinct of palms.

It is proper to say, in closing this article, that due consideration should be given to location, character of soil, known liability of biting frosts, or general exemption, and of equal importance in the planting of species of doubtful hardiness is the selection of good, strong plants, pot or box-grown, and planting should be done not much earlier than April, nor delayed much beyond May. A long summer is thus assured, during which the subject may become well established.—J. C. Harvey in Rural Californian.

Mechanical Progress.

Saving by Firing with Oil on Steamers.

An English inventor claims, says the *American Manufacturer*, that, with his system, he does with one ton of oil that which three tons of best coal are required, which means a great saving of space. Taking the average price of coal on "all-around" at 25s per ton, and oil-fuel at 50s per ton, the following comparison is obtained:

COAL.	
Coal (600 tons at 25s per ton).....	£750
Stokers (say 9).....	168
	£918
OIL-FUEL.	
Oil-fuel (200 tons at 50s).....	£500
Oilmen (3).....	56
	£556
Gain by using oil-fuel:	
Less cost of fuel and stokers.....	£382
Cargo (ex-coal space) 270 tons at 40s.....	540
	£922

So that, if as at present with coal-fuel, a steamer should only just pay its expenses, by the use of oil-fuel a considerable profit would occur, in addition to other advantages.

In a steamer specially designed for oil-fuel, the double bottom may be used as "bunkers" for the oil-fuel, thus allowing the space usually set apart for carrying coal to be used for carrying freight, and so augmenting the carrying capacity of the steamer.

Where oil-fuel is used, stokers practically are not required, because there is no stoking, fire-cleaning or coal-trimming required, and a few men would replace any army of stokers.

After the fires in the boiler with oil-fuel are started, the doors of the furnace are never opened, so that there is no loss of heat, as is the case with coal by frequent opening of the doors for stoking and cleaning of the fires, when the cold air is unlimitedly admitted, prejudicial also to the endurance of the boilers from rapid expansion and contraction.

An experiment recently was made on a steam-yacht in France, where residuum was used as a fuel. During the travel one man was able with ease to run the engine and care for the fires. A little more than one-half the amount of fuel was consumed which would be used if coal had been the fuel. The trial proved that the relative movement of oil and coal required for the same work was as 4 to 7.

Other and more important experiments were made at Cherbourg and Toulon, extending over a period of several months.

The trials are reported to have shown that, by using coal in the customary way, with natural draft, and supplementing it with petroleum in the proportion of about 15 or 20 per cent of the total weight of both kinds of fuel burned, the boiler-power can be increased by about 20 to 22 per cent, taking as a standard the performance of the boiler when using coal alone with clean fires and with natural draft. This proportion of petroleum gave the best results obtained, from the standpoint of economy.

In the case of a vessel having only a moderate forced-draft power, it was found that, increasing considerably the proportion of petroleum burned, the highest power obtainable was practically the same as could be developed with forced draft when using coal alone. While using petroleum no special means were employed to give a stronger current of air than usual.

But as the definite result of the tests made, the conclusion was reached that vessels having closed fire-rooms and thoroughly efficient forced-draft appliances can develop a much higher power by burning coal alone, with forced draft, than by using any of the methods which formed the subject of experiment.

At the same time the trials are regarded as having demonstrated the value of petroleum for use as an auxiliary fuel in connection with coal. The mixed fuel, as it has been termed, would enable boilers to respond promptly to sudden demand for an increased amount of steam and would afford a means of keeping up a relatively high speed for several days without resorting to the use of forced draft and without subjecting the fire-room force to any undue strain.

Big Locomotives for Mexico.

The biggest and most powerful railroad locomotive in the world, according to *Locomotive Engineering*, will soon be running on the Mexican railroad. It was constructed at the Rhode Island Locomotive Works, with a couple of like companions. The monster weighs 130 tons when in working order, and was built to climb steep grades in the mountains of Mexico and to drag heavy loads around sharp curves safely. The engine looks like a couple of loco-

motives of the "mogul" pattern backed up together, with the two cabs joined. It is an odd form and was constructed after a design by superintendent of machinery F. W. Johnstone, of the Mexican Central, who realized that a special style was necessary for the work to be performed on his railroad. The idea was to secure a motor with flexibility sufficient to go round the sharp curves with least frictional resistance. This flexibility is gained by securing the driving-wheels in a truck which is free to move in a line different from that followed by the main frames.

The cylinder and boiler in the Mexican Central Goliath are carried on the main frames separate from the driving-wheel trucks. As the cylinders are not in line with the driving-wheels in rounding curves, it is necessary that a special method of transmitting power from the cylinders to the crank-pins should be employed. This is done in a very ingenious way through levers that transmit the power, and compensate for the varying distances between the pistons and the crank, due to the swiveling of the driving-wheels. But for this compensating arrangement it would be necessary to give the engine so much cylinder appearance that the loss of steam would be very great. The power-transmitting levers are seen at the back of the cylinders, connected at the top by a short link, and the bottom ends pinned to the front end of the main rods. There are two of the latter, one connecting with a crank-pin, the other with a return crank. The piston transmits motion to the back one of the two levers, and that gives motion to the front lever, which is fulcrumed securely to the frame near its center.

The engines are compound, with annular cylinders, the high-pressure cylinder being in the middle and the low pressure cylinder outside. The high-pressure cylinder is 13 inches diameter and the low-pressure 28 inches. The stroke is 24 inches. It is calculated that the cylinder capacity of each pair of cylinders is equal to a 19x24 simple engine.

The boilers are of Otis steel, 9-16-inch in diameter, and carrying 180 pounds of steam to the square inch. They are 54½ inches in diameter, and have 201 two-inch tubes, 15 feet 9¼ inches long. The fireboxes are of the Belpaire type, 56 inches long and 56 inches wide.

The arrangement of working is that the valve-motion of the two engines is operated by one screw reverse lever.

In the new locomotive the engineer sets on one side of the cab with all the necessary apparatus for working the double-ender within easy reach. On the other side the fireman pours in the fuel through side doors. A coal-passer is necessary to aid him.

SELF-HARDENING STEEL.—There is little doubt but that there is considerable misunderstanding among machinists regarding the use of self-hardening steel. It is quite common to resort to this steel where the ordinary carbon steel used in the shop does not stand well, or refuses to cut; then if the self-hardening steel does not work it is considered that every resource has been exhausted. The fact is, however, that while it is true that self-hardening steel will often do good work where the ordinary steel fails, or is unsatisfactory, carbon steel of high grade and high carbon can be and is made and hardened in the usual way, that will readily cut metals that no self-hardening steel can make an impression upon. It is said a number of coarse files or rasps have been piled upon each other to a height of 12 inches, bound together with wire and drilled through from top to bottom of the pile without lubricant. This was not done by a drill made of self-hardening steel, nor of such common steel as is too often supplied by purchasing agents who give far more attention to discounts and commissions than to quality of the steel they buy, but by high-grade carbon steel made especially for use in such a test. Mushet or self-hardening steel is all right in its place, but there are places for which it is not adapted, and it is best, both for makers and users, that the proper place and uses of the different kinds of steel should be understood.—*American Machinist*.

COST OF NAVAL VESSELS.—The awarding of the contracts for building the new warships "Brooklyn" and "Iowa," to Messrs. Wm Cramp & Sons, for \$2,986,000 and \$3,010,000, causes Secretary of the Navy Tracy to remark on the late reduction of price for this class of work. The prices here quoted are from 10 to 12 per cent less than for any previous ship of their class. The "Brooklyn" will be larger by 1,036 tons than the "New York," and the cost will practically be the same for both. This reduction is due to the sharp competition of at least four well equipped ship-building firms, the Bath Iron

Works, of Bath, Me.; Wm. Cramp & Sons, of Philadelphia; the Newport News Ship-building Co., of Newport News, Va., and the Union Iron Works, of San Francisco.—*Engineering News*.

Scientific Progress.

Hunicke's Process for Smelting Silver Lead Ores Containing Zinc.

The problem of finding an economical process for smelting zinc-bearing silver lead ores in which the galena and zinc blende are intimately mixed is attracting a good deal of attention among metallurgists at the present time. This process recently devised by Mr. H. A. Hunicke will, therefore, be of considerable interest to our readers, although time has not yet been allowed for proving its final commercial value.

The process consists in heating up separately the roasted ore and the coke to about the temperature at which zinc oxide is reduced to metallic zinc by carbonic oxide, and then charging thin layers of each alternately into a cupola furnace. The lead is reduced to the metallic state and runs, together with the silver, to the bottom of the furnace. The zinc is reduced to the metallic state and volatilized, and after escaping from the heated mass is rapidly oxidized again by the gases. The vapor thus formed is led to a condensing chamber, where it is deposited as zinc oxide powder. The reduction of the lead and zinc is effected almost immediately after the introduction of the ore into the cupola furnace, owing to the smallness of each charge, and also to the fact that the ores have been previously heated to the temperature at which the zinc ore is reduced by carbonic oxide. Thus the zinc vapors have no opportunity to clog up the coke and prevent further combustion.

This process differs from the usual one in the previous heating of the ore and fuel, and in the smallness of each charge. Apart from more ready freeing of the zinc and prevention of clogging, the chemical process is the same all through, and the chemical losses of lead and silver are practically the same. There will, however, be more heat expended in heating the two separately and charging them hot, and more labor will be necessary in charging them often and in small quantities. If the ores are brought to the cupola furnace direct from the roasting furnace, some expenditure of heat would be saved, but there would be considerable difficulty in making the output of the two furnaces correspond.

The condensation of the zinc oxide can be carried out to as great a stage of perfection as is commercially profitable. Mr. Hunicke estimates that it is quite feasible to obtain 60 per cent of the metallic zinc when ores containing 16 per cent are worked with.

An objection which may be urged against the process is that it requires a constant uniformity in the chemical composition of the ores. So far no such difficulty has arisen in actual practice, as all ores can be treated satisfactorily. On whatever ores Mr. Hunicke has worked good results have been obtained, and an extra \$5 or \$10 per ton of ore has been realized by the recovered zinc oxide. No doubt the process will have to be adapted to each separate ore on which it is employed, but there is little doubt of its applicability, for it attains an end hitherto unattained—the separation of zinc without fouling the coke.—*Engineering and Mining Journal*.

New Process for Making Gas.

After years of hard study and experimenting, L. C. Parker, of Liberty, Ind., has discovered a process for the manufacture of gas that is attracting the attention of men interested in the gas question all over the country. The gas is essentially an oil water-gas, steam being decomposed, and the results, hydrogen and oxygen, are then carbureted with crude petroleum, passing through a mass of fret-work of firebrick, which, heated to a high temperature, is made into a fixed, noncondensable gas. The process is remarkably simple and easily operated.

In September, says the *Chicago Journal of Commerce*, Mr. Parker began the construction of his test plant, which was completed ready for operation the first of December. Since then the gas has been tested under the most trying circumstances. The results have been most satisfactory. The mains were laid in frozen ground and are lying in the trenches exposed to the coldest weather experienced there for years, the thermometer ranging from 10 to 22 degrees below zero. The gas has resisted all forces which so easily congeal other gases. This is thought to prove that

the Parker Gas is noncondensable. The gas is being used for cooking, heating and illuminating purposes, and shows a heating energy equal to natural gas, there being over 800 heat units per cubic foot. When used for illuminating purposes it gives a diffusive, brilliant light, emitting no smoke or smell, and when tested shows from 22 to 26-candle power. From each 100 barrels of crude petroleum used, from five to seven barrels of the best grade tar asphalt are obtained, which has a market value of from \$4 to \$5 per barrel, and it only requires seven to eight gallons of oil to produce 1000 cubic feet of gas. The asphalt is easily extracted from the boiler where it accumulates. The heating power of the gas is so intense that a small radiator, that is only three feet long by three feet high, keeps the temperature in four large rooms up to 75 degrees when the mercury is below zero. Gas men are coming from everywhere, and all who have investigated and have witnessed its testing pronounce the process a wonder.

Testing Oxygen.

The following simple method of ascertaining the quantity of free oxygen present in mixed gases was described some time ago in *Siftings*. Collect some of the gas in a test tube or in a graduated eudiometer inserted in a basin of water. Bring the water within to the same level as that without, and then hold the tube steady while inserting an accurately-fitting rubber stopper. After noting the volume now occupied by the gas withdraw the stopper (while the open end of the tube is under water of course) and introduce a piece of caustic potash into the tube. Cork it up again immediately, and shake for a few minutes or until the caustic soda is completely dissolved. Then remove the stopper to permit readjustment of the water level. Any contraction that has taken place is due to absorption of carbonic acid. Next wrap a few grains of pyrogallol acid tightly in a single fold of paper, and introduce this similarly to the caustic potash, and so quickly as to prevent the escape of any considerable proportion of that substance. The absorption now observed, which is accompanied by blackening of the potassium pyrogallate solution, represents the amount of free oxygen in the gas under examination, with sufficient accuracy for many commercial purposes. In testing nominally pure oxygen, it would be better that the measurement of the gas should be taken while holding the tube by its immersed end, and while the hydrostatic pressure is equal within and without the tube. Besides, the reading for carbonic acid, which is anyhow pretty rough, owing to the solubility of that gas in water, may be omitted. If pills containing pyrogallol acid within an impervious but soluble coating were made they might probably prove a saleable article to intelligent purchasers of compressed oxygen.

The Action of Alkalies on Glass.

The following facts concerning the action of solutions of alkalies and acids upon glass have been collected from the results obtained by F. Foerster and others who have experimented in this direction, and are published in the *Chemical Trade Journal*:

1. Solutions of caustic alkalies act upon glass much more strongly than water, since, except in very dilute solution, they dissolve all the constituents of the glass as such.
2. Of the caustic alkalies the most active is caustic soda, then follows caustic potash, and then ammonia and baryta water.
3. Rise of temperature increases the action of the alkalies very considerably.
4. The action of the alkaline solution increases with the concentration, at first rapidly, but afterward only very slowly.
5. Highly concentrated solutions at the ordinary temperature have less action than more dilute ones.
6. Pure alkaline solutions, not too highly concentrated, have less action upon glasses than such as have been rendered impure by small amounts of silicic acid.
7. Alkaline carbonates, even in very dilute solutions, attack glass much more strongly than water. Their mode of action corresponds rather with that of other salts than with that of the caustic alkalies. In equivalent concentration solutions of sodium act more powerfully than those of potassium carbonate.
8. The action of salt solutions upon glass is made up in a manner which varies with the concentration and the kind of salt, of the action of the water itself, and that of the salt which is present.
9. Both these modes of attack are differently influenced by composition of the glass.
10. These salts act more strongly than water whose acids form insoluble lime salts. The action of these increases with concentration.

Electricity.

An Electric Torpedo Detector.

An important demonstration has just been made in England, says the *Electrical Review*, of the possibilities of an ingenious electrical and telephonic apparatus for defending roadsteads, anchorages and mine fields by giving warning by visible and audible signals on shore of the approach at night or during thick weather of torpedo boats or other hostile vessels. The experiments in connection with the invention, which is credited to an American, Captain McEvoy, the torpedo and submarine expert, formerly attached to the Confederate army, have extended over several weeks, and have been supervised by a representative of the War Department and a committee of the royal engineers. The instrument employed is called a "hydrophone," and consists of two parts. One part is placed at the bottom of the water, outside the anchorage or mine field, at a depth of from five to fifteen fathoms, and the other is fixed at a station on shore, and the two are electrically connected by cable at distances of from one to five miles. In the demonstration referred to, the instrument was sunk in seven fathoms and about 300 yards from the shore.

The submerged part consists of a bell-shaped iron case, three-fourths of an inch thick, 20 inches in height and extreme diameter, and weighing about 340 pounds. At the top is fitted a sensitive vibrator or diaphragm enclosed in a copper box. It is formed of a plate of ebonite with carbon attachments, and when the case is submerged the delicate mechanism is kept clear of the water by means of the column of compressed air, which is enclosed, as in a diving-bell. As a torpedo boat approaches within a radius of half a mile, or a man-of-war within a mile, the pulsations of the propeller produce a vibratory motion inside the case. These vibrations are transmitted to the station on shore in the following manner: The electric current from the land battery passes through the vibrating mechanism, and also through the apparatus on shore, in the circuit of which is placed an instrument called a kinesiograph, which is somewhat of the nature of a galvanometer.

By means of this the movements in the water are communicated to a needle flickering in a graduated arc, and when the oscillations become pronounced the needle is clutched by a magnet at the end of the arc. This makes contact, and the vibrations in the submerged case are made visible and audible by means of flashing light, the firing of a gun and the ringing of a bell. Telephonic signals are also transmitted through the same current. For coast defenses a number of hydrophones could be sunk in the approaches to a port or dockyard, and warning would thus be given to the neighborhood of an enemy; but, besides this, it is proposed to make the hydrophone useful in dangerous zones, around headlands that are frequently fatal to shipping in dense fogs. A danger zone could be connected by means of the hydrophone with the nearest coast-guard station; and a ship would be warned of the danger into which it was running by the automatic firing of a gun or the flashing of a light.

Pruyn Elevated Electrical Railway.

Various systems of rapid transit, in which only one rail was to be used, have been proposed from time to time, but no practical system seems to have been evolved, although experimental roads have been constructed and operated for a short period. Mr. Henry S. Pruyne, of Hoosick Falls, N. Y., has devised a system which he claims overcomes all the difficulties which have hitherto been encountered, and which renders entirely practical this very interesting form of construction. Mr. Pruyne is making efforts to have his road constructed on the World's Fair grounds and exhibited in actual operation during the exposition.

The accompanying description from the *Electrical World* will give a clear idea of the elevated structure, the form of the cars and the various details of the system. The track consists of one rail carried on the top of single girders placed at proper intervals. The cars are operated by electricity, which is supplied by the double-trolley system. The conductors are carried under the lower flange of the rail, where they are entirely protected from mechanical injury, as well as from the effects of the weather, and from dust and dirt. There is also space under this flange for the suspension of telephone, telegraph, or electric-light wires, which would not be subject to the annoying effects of induction that would be noticed if only one wire and the ground return were used. The carwheels come up into the center of

the car, and the seats for the passengers are arranged lengthwise of the car, back to back, with sufficient space between them and the sides of the car to allow of the passengers and the motormen easily moving from one end to the other. The passengers enter the cars by doors at the sides, but doors at the end are also provided for the convenience of employees. The carrying-wheels bear the car by the means of heavy pins with spring bearings, upon which the weight of the car rests. The car is of much lighter construction than would be possible in any other form, while at the same time it possesses the necessary strength and rigidity. Thus, not only is the center of gravity very low, but it is even below the surface of the rail, which destroys the tendency of the car to tip from one side to the other, or to leave the track. This form of construction renders a much higher speed possible than would be safe with any ordinary car. The current is taken from the conductors by means of two wheels, which also serve as guide-wheels, and form an additional safeguard against the car leaving the track. Good contact is always secured without undue friction.

One of the advantages claimed for the Pruyne system is, that flange friction is done away with to a large extent, and that on rounding curves there is none of the sliding friction which always takes place in a double-rail road. The motion at high rates of speed is also said to be very much easier than in the ordinary steam railroad, or even in electric roads, as there is none of the swaying or vertical motion.

The structure does not interfere in any way with surface roads, or prevent the land which it crosses from being used for agricultural purposes any more than a row of trees would. No grading, ballasting, draining, fencing, and no culverts, telegraph poles, or small bridges are necessary. The advantage which it possesses over the ordinary elevated structure is, that it does not disfigure the street nearly as much, and does not in the least darken it. The objectionable noise is also avoided to a large extent. On account of its great simplicity this structure can be built at a very small cost, and the expense of keeping it in running order is exceedingly low.

This road, of course, possesses all the advantages which other electric systems claim, so that collisions are impossible and accidents from switches and drawbridges can be avoided. The speed which can be obtained by this form of car could be very high, and consequently the inventor urges it as a very practical system of rapid transit, not only in cities, but for the connection of towns and distant points.

The Naval Search-Light.

Electricity has added an almost incredible percentage to the efficiency of our naval establishment, and the rapidity with which it has been adapted to purposes of warfare, and the completeness of the revolution it seems to be making in methods, are fairly marvelous. The search-light alone almost doubles the capacity of the ordinary ship of war.

When the British bombarded Alexandria, the search-lights on the vessels composing the squadron served not only to make the harbor as light as day on the darkest night, but enabled the admiral to observe the operations of the enemy on shore in the construction of batteries and earthworks, thus placing the Egyptians at a decided disadvantage.

It will enable a vessel to engage the enemy at night to almost as good advantage as during the day. It is useful in chasing a flying enemy and in conducting the management of a fleet. The assistance it gives in reconnoitering a coast will be readily appreciated. Difficult movements, such as entering a tortuous channel by night, passing between the vessels in a crowded harbor, and making a landing when the saving of time is of supreme importance, are all rendered comparatively easy by the search-light.

The search-lights of the British squadron at Gibraltar were the means of saving hundreds of lives when a merchant steamer sank in that harbor a few months ago. An effective search-light will make it almost as difficult for a torpedo boat to reach a warship by night as it is by day. Indeed, so difficult does it render the attempt that it has now been decided that the torpedo vessel and everything belonging to it, even to the faces of the men, must be painted black to avoid discovery.—N. Y. Advertiser.

THE business of raising large horses in Canada for export to street railway companies in the States has nearly disappeared since the introduction of the trolley system.

Useful Information.

Cost of Street Cleaning.

Estimates for cleaning the streets of New York and removing ashes and garbage during 1893 place the total cost at \$2,569,253. The total appropriations for this purpose thus far in 1892 have been \$1,093,355; about \$188,000 having been granted since the annual appropriation was made. The estimates for 1893 are distributed as follows:

Administration office force of 24, and supervisory force of 146, \$293,970; sweeping, 1,575 sweepers, 150 machine and water cart drivers, all at \$600 per year, and sundries, \$1,085,000; carting, 675 drivers at \$600 each, hostlers at \$720, shoeing and feeding 950 horses at \$182.50, and sundries, \$671,815; removal of snow and ice, \$40,000; final disposition by means of tugs and scows, \$322,800; new stock, as horses, carts, harness, etc., \$197,338; rentals and contingencies, \$58,330. The salary list varies from \$6,000 for the commissioner of street cleaning to \$600 for sweepers. The city is now divided into eleven districts, each under the charge of a superintendent. There are fifty-eight cleaning districts, each under the charge of a foreman. The superintendents and foremen are each responsible for the cleanly condition of the districts under their charge, and the sweepers are also held responsible for the length of street which it is their duty to sweep. During the first eight months of 1892 there have been removed a total of 1,260,221 loads of dirt, against 1,135,045 during the same period of 1891, an increase of 125,176 loads, or about 11 per cent. The new street cleaning law provided for 1,500 sweepers, 750 drivers and 88 hostlers on the start, with an addition to the force of 5 per cent per year. The commissioner, Mr. T. S. Brennan, reports that the system is efficient, but that while the advisory committee which formulated the new law thought the above force would be large enough at the start to clean the whole city, it has been found that at least twice the number of sweepers are required to clean all the paved streets and avenues, allowing one sweeper to each 600 or 800 feet of streets, according to width. The down-town streets are principally cleaned by hand and the upper part of the city by machines, operated at night.

Before the Clermont.

It is not generally known that the first steamboat ever built in the United States was partly constructed in Frederick county in the year 1785. The vessel was built by James Rumsey at Shepherdstown, W. Va. Robert Fulton with his Clermont was anticipated by Rumsey twenty-two years. The steamboat was fitted up with machinery partly manufactured at the Catocin furnace of the Johnson Brothers, near Frederick. The boiler, two cylinders, pumps, pipes, etc., were manufactured in Baltimore. Some portions of the works were made at the Antietam Iron Works. On March 14, 1786, a public experiment, the first ever undertaken in America, was made on the Potomac river. Rumsey succeeded in attaining a speed of four miles an hour against the current.

The steamboat was eighty feet long. It was propelled by a steam engine, which worked a vertical pump in the middle of the vessel, by which the water was drawn in at the bow and discharged through a horizontal trunk at the stern. The boat bore a load of three tons. The weight of its machinery was 666 pounds. The whole of the machinery, including the boiler, occupied a space but little over four feet square. Two distinguished men were patrons to Rumsey's experiment—George Washington and Governor Thomas Johnson of Maryland. The experiment was made in the interest of the proposed Chesapeake and Ohio canal. Rumsey clearly and satisfactorily demonstrated that a boat could be propelled up stream against the current.

Thus we find that the first steamboat was propelled on the Potomac and a portion of the first machinery made in Frederick county 107 years ago.—Frederick News.

Mustard.

A writer in the *Pharmaceutical Record*, describes as follows the manner in which mustard is prepared for use as condiment, giving the results of his experience while in the employ of a leading spice-grinding firm:

The mustard seed used was a mixture of the white (California or European), two parts, and black (Trieste), one part; these were put through a winnowing machine to remove dust and other accidental material, and then ground together. The ground cake is then expressed to remove the fixed

oil (mustard oil), again ground and then sifted twice. The resulting powdered mustard is not more than one-half the weight of the original seed employed, the color a grayish or ashen color, more like corn meal.

A record of one lot, showing materials used and entire product, will not be without interest: 1946 pounds (1300 pounds white mustard, 646 black) were cleaned and ground separately, the cakes, weighing respectively 1273 and 640, equaling 1913 pounds, a loss of 33 pounds. When pressed the yield of oil was 204 and 128, equaling 332 pounds. Subsequent sifting removed the hulls of the seed; the amount of powdered turmeric used to give it the desired color was four pounds, and the entire yield of ground product suitable to sell as pure ground mustard was 887 pounds. There was left 124 pounds of what was known as "tailings," which probably would, when mixed with the next lot, utilize about 30 pounds of mustard, but which could not be separated without adding comparatively too much cost to make it worth while.

The loss, therefore, in making a pure mustard from the seed will average one-half of the material used—1946 pounds original quantity; total product of ground mustard, 887 pounds. The oil, 332 pounds, equaling 44 gallons, is valued at about 60 cents a gallon, so that the total loss in dust, valueless husk, etc., is 727 pounds, which cannot be utilized except as the miller uses it as fuel.

Even a pure mustard may vary greatly in taste and effect. White mustard alone has nothing like the pungency of either the black or a mixture of the two varieties. Like the bitter almond or the peach kernel, the pungent volatile oil is not developed until it comes in contact with water, so mustard does not yield its pungency to alcohol, but to water. A pure ground white mustard is deficient in pungency; the black develops it without the mixture of the white, but when blended as suggested above it is much more acceptable than either alone.

Thirty Miles an Hour.

C. D. Mosher, the designer of the fast craft Norwood and other triumphs in the line of steam yachts and launches, is now completing a world-beater. It is a 78-foot boat, with 9 feet 6 inches beam, and it will greatly disappoint him if it does not exceed 30 miles an hour. The designs of boat, engine and boiler are all Mr. Mosher's personal work, and certain novel details of the boiler and engine are covered by his patents.

The engine is declared to be a marvel of lightness combined with power in compact form. It has just been completed by Lyndner Wright of Newark, and has been tried in his shop. It is of the quadruple compound type, with cylinders in a straight line, supported over an elliptical base of cast and wrought iron by means of slender steel vertical pillars, each pair of which is braced with straining rods in the form of an X split down through the point of crossing, and provided with a screw by which the braces can be strained until all racking is obviated. The stroke of the engine is 10 inches, and the cylinders are respectively 9½, 13½, 18 and 24 inches in diameter. Every ounce of superfluous metal has been removed from the castings forming the cylinders, and they are handsomely jacketed with sheet brass.

It is estimated that the complete engine will weigh less than 3600 pounds, and that at a speed of 500 to 600 revolutions it will develop from 500 to 600 horsepower, with a steam pressure of 250 pounds. It is said to be the lightest engine of its capacity in the world. To insure the minimum of weight with the maximum of strength, all of the working parts have been reduced to the smallest practicable dimensions, or are relieved of superfluous metal at the center by boring. The rock shafts have one-inch holes through them. The piston and connecting-rods are hollow, and the big crank shaft has been bored out wherever a tool could be used upon it. This shaft was carved out of a solid steel forging weighing 2012 pounds. It now weighs 414 pounds, and is a handsome piece of work. The crank-heads and shoulders are gracefully rounded. It required six months of steady work to make this shaft and over eight months in all to build the engine. When set up, it will occupy less than 14 square feet of floor space.

The boiler is under construction at the Hewes and Phillips Iron Works on the Passaic, in Newark. It is a pipe boiler of peculiar construction, and is built with a view of standing great pressure, occupying little space and steaming rapidly. When the Passaic river opens, the boat will be towed to the Hewes & Phillips wharf and then fitted with boiler and engine.

Blinn's Tin, Sheet-Iron and Copper-Plate Worker.

A New, Revised and Enlarged Edition, from New Type, with New Engravings.
One of the Most Popular Technical Books ever published in the United States.

A PRACTICAL WORKSHOP COMPANION FOR TIN, SHEET-IRON AND COPPER-PLATE WORKERS.

Containing rules for describing various kinds of Patterns used by Tin, Sheet-Iron and Copper-Plate Workers. Practical Geometry, Mensuration of Surfaces and Solids; Tables of the Weights and Strengths of Metals and other Materials; Tables of Areas and Circumferences of Circles; Composition of Metallic Alloys and Solders, with numerous valuable Receipts and Manipulations for every-day use in the workshop. By Leroy J. Blinn. A new, revised, and enlarged edition, printed from new type, and with 170 newly engraved illustrations.

In one volume, 12mo, 296 pages, price \$2.50, free of postage to any address in the world.
It having been found necessary to make a new set of electrotype plates and new engravings of this most popular book—the old ones having been worn out by actual use—it was determined to have the book reedited and to add to it, in the different departments, new, recent and necessary matter. All of the old illustrations of patterns have been retained, and new ones have been added. The portion treating of metallic alloys and solders has been entirely rewritten, so as to have a more systematic arrangement, and to bring it abreast with the best modern practice in this interesting and important field. In all the other departments new matter has been added, every effort having been made to render the entire work, in the future, if possible, even more useful to the tin, sheet-iron and copper-plate worker than in the past.

ABSTRACT OF CONTENTS.

Rules for Describing Patterns; Practical Geometry; Mensuration of Surfaces; Mensuration of Solids, and Capacities of Bids; Tables of Weights, etc.; Tables of the Circumferences of Circles and of the Areas of Circles; Rules for Rendering the Tables Useful; Size of Tinware; Capacity of Cylinders, and various other Useful Tables and Information; Practical Receipts, Varnishes, Lacquers, Cements, Metallic Alloys, Miscellaneous Receipts; Index of Materials, with Tables. Index.

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

A circular of 4 pages, quarto, giving the full Table of Contents of this popular Book, will be sent free of postage to any one in any part of the world who will furnish his address.

Our new and enlarged Catalogue of Practical and Scientific Books, 88 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying, working precious ores on the Pacific side of the American Continent. He writes thereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements: Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations well bound in cloth; 1899. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—JUST OUT.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I. It treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

WELL MACH'Y All kinds, Water, Gas, Oil, Mining, Ditching, Pumping, Wind and Steam Heating Boilers, &c. Will pay you to send 25c. for Encyclopedia, of 1500 Engravings. The American Well Works, Aurora, Ill., also, Chicago, Ill.; Dallas, Tex.; Sydney, N. S. W.

The World's Fair Yachts.

The fleet of water craft to navigate the lagoons and basins at the fair is now calling for the labors of 200 or 300 shipwrights. The 50 electric launches for the lagoons are being constructed at Detroit and Racine. The larger boats for the basins and naval exhibits, commodious steam yachts in size, machinery and appointments, occupy the stocks in the shipyard of Charles P. Willard & Co. of Chicago, on the north branch of the Chicago river. There are 12 of these steam yachts, exactly alike above the water line. Alongside of them are five larger boats, all designed for World's Fair traffic next season. If there is time a half-dozen more will be constructed before the opening of the fair. The later additions will be smaller and have less engine power.

When Mr. Willard secured the concession of running boats on the basins he was confronted with the question of what he was going to do with a dozen boats after the fair was over. At best they would be second hand, and must be disposed of at some price. It could not be hoped that the profits of the World's Fair season, after handing over 25 per cent of the gross receipts to the Exposition Company, would be large enough to offset a big depreciation.

Acting on this idea, the boats were designed to be large and stanch. The exposition fixed the limit of length at 50 feet, and Mr. Willard took the limit.

Outside of the machinery the dozen boats for the basins and the five larger yachts are now nearly completed. The 17 standing side by side on the stocks make a pretty sight, even on a cold day with the wind and snow blowing though the chinks in the huge shed. On some the permanent cherry and mahogany awning is being fitted. On a pleasant day next April the procession will steam out of the North Branch and down Chicago river to the lake. No finer fleet of steam yachts ever specked Lake Michigan than will be these boats as they hug the shore on their way to Jackson Park.

When the first boat was completed, with the exception of machinery, Mr. Willard made a temporary launch. The boat was towed to a stone derrick by the river side, and exactly 29,500 pounds of stone was lowered into the boat. Just two feet of its white side was out of water. Although the displacement had been carefully figured, still there might have been an error, and the shipbuilder was taking no chances. Counting the machinery, fuel and permanent fittings to weigh five tons, the boat would have a carrying capacity of ten tons. This left a wide margin for the local steamboat inspectors, who passed on the plans and fixed the Government limit at 75 passengers.

All 17 boats will have triple-expansion engines exactly alike. The cylinders will be 4½, 7 and 12 inches in diameter, with 8-inch stroke. The boilers will be the Roberts safety water-tube style, to stand the Government test of 200 pounds pressure to the square inch. Running wide open, the machinery will develop 100-horsepower. With the ordinary cut-off of steam they will show an economical working force of 83-horsepower. This is in excess of the requirements at the fair, as high speed will not count for much in the short runs, but after the fair is over a good 12-mile boat will be much more salable than one of less speed. The machinery alone will cost over \$3000 for each boat.

The World's Fair yachts are built with rather bluff, straight bows, and are intended to sit squarely in the water. The boilers and engines are amidships, and are low down in order to lower the center of gravity. A cabin, the roof of which is three feet above decks, will cover them. The steering-wheel will be in the open space at the bow. Awnings, supported by permanent frames, will extend the entire length. The engines have bronze connecting rods and will be highly ornamented. They will run without noise, and, as the furnaces will use hard coal, the boats will be pleasant for sightseeing. The planking is of oak and white cypress, 1 and 1½ inches thick. The frames are of oak. Brass openings, with automatic valves, take the place of the usual "scuppers" by which water runs from the deck on a heavy sea.

The five larger steam yachts are trim in model. They are 66 feet keel, 74 feet long over all, and 10½ feet wide. They will have a cutter bow, with bowsprit, and two spars, fore and aft. Being extremely sharp, they will have greater speed on the same power than the shorter boats. The boiler and engine will be housed in, but otherwise the decks will be free. Awnings, held by the spars, will be their covering. The rail is handsomely paneled in quarter-sawn oak. These yachts will cost about \$7000 apiece. They will be for charter during next sum-

mer to private parties, who prefer that way of going to Jackson park.

Already clubs are being formed among residents of the North Side to charter or buy steam yachts for next season. The example of the Buena Park Club in having its own steam yacht, has called general attention to the pleasures of yachting on the club plan, and Mr. Willard has prepared for quite a craze in that direction by having speedy and commodious boats, which can be chartered by those who do not care to buy. The five will be ready for service at the same time the dozen will sail for the fair-grounds.

How the Telephone is Managed in Roumania.

The two Roumanian cities, Galatz and Braila, on the Danube, were lately connected by telephone, which is, like the telegraph in that country, an institution of the State. Before its opening, an ordinance of the Government for its use was published in the official gazette, the principal part of which is as follows:

"A person who wishes to communicate with another by telephone is bound to notify that person beforehand by letter, telegraph or otherwise."

A dealer in produce in Braila was about to close a contract for a supply of barley. He desired, however, to learn beforehand the price of the barley quoted at the Board of Trade in Galatz. For that purpose he went to the telephone office, and, after the fee, desired to get telephone connection with his correspondent in Galatz.

"Very well; have you informed that gentleman?"

"What for? He is in Galatz, and the person to whom I want to telephone."

"That would not do, sir. Here is the ordinance. Before you can telephone to him, you must inform him beforehand by letter, telegraph or in any other way."

"Nonsense! Is the Government crazy? Maybe they ask me to travel to Galatz and inform him that on a certain day and hour he may be at the telephone office to receive a communication from me?"

"Yes, that would do, too," the official said.

The merchant was obliged to give up his barley deal.—Electrical Review.

RAILWAY MILEAGE.—Railway mileage in the United States on June 30, 1891, was 168,402.74 miles. This figure indicates the length of single track mileage, the total mileage of all tracks being 216,149.14 miles. The length of single track per 100 square miles of territory, exclusive of Alaska, was 5.67 miles, and the length of track per 10,000 inhabitants was 26.29 miles. Some of the States are exceptionally well provided with railway facilities, as may be seen by the table of the report which shows the length of line in the several States per 100 square miles of territory. Such assignment shows for Connecticut 20.77 miles, for Delaware 16.10 miles, for Illinois 18.25 miles, for Iowa 15.12 miles, for Massachusetts 25.99 miles, New Jersey 27.71 miles, for New York, 16.19 miles, for Ohio 19.68 miles, for Pennsylvania 22.77 miles. The only countries in Europe which have an excess of 10 miles per 100 square miles of territory are Germany with 12.77 miles, Great Britain with 16.52 miles, France with 11.23 miles, Belgium with 28.71 miles, Holland with 13.83 miles, and Switzerland with 12.43 miles. No country in Europe, Sweden alone excepted, has 10 miles of railway per 10,000 inhabitants.—Interstate Commerce Commission.

OIL LANDS AND MINING LAWS.—The oil men of California are much disturbed over a bill introduced by Senator Stewart in December, 1891, affecting the mining law, and reported back by the Committee on Mining in February, 1892, with amendments. The bill describes how locations shall be made, how much assessment work shall be done each year, how patents can be secured, and restricts the area of placer claims to 40 acres. The Committee on Mines placed petroleum land in the same category with the placer ground, and the feeling of the oil men is best told in a telegram just received by Congressman Bowers, as follows: "Senate bill 54 has been sent to the House. Have all action deferred until the petroleum oil miners can be heard. The bill, if passed, will stop the industry in public mineral land. Oil ground cannot be held or worked at a profit in 40 acres, or any small tract, as proposed by the bill. A complete showing can be made by sworn evidence and Government reports that the bill should not pass." It is not probable this bill will pass this session at any event.

Charlemagne was said to be the best player at checkers of his century.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISSELL, 650 Market Street, Chronicle Building, San Francisco.

NEW DISCOVERY

Mines Revived and Miners Enriched
By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. TABOR, Pres.; LEONARD GOW, V. Pres.; H. A. JONES, 2d V. Pres.; P. OEO. GOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Sec'y; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
The Cassel Gold Extraction Co., Limited, Glasgow, Scotland, and also in Australia, South Africa, New Zealand, Queensland, Etc.

General Office of Company:
Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livestock Gold Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champion's Mines, Humbug District, Yavapai County, Ariz.; The Crowned King and Last Chance Mines, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Co., Old Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the MacArthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process. If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver. We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubs especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton. The most desirable class of ores for this process are the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,
Gen. Mgr. and Secretary.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old
experienced, first-class Agency. We have able and trustworthy Associates and Agents in Wash-
ington and the capital cities of the principal nations of the world. In connection with our edi-
torial, scientific and Patent Law Library, and record of original cases in our office, we have
other advantages far beyond those which can be offered home inventors by other agencies. The
information accumulated through long and careful practice before the Office, and the frequent
examination of Patents already granted, for the purpose of determining the patentability of
inventions brought before us, enables us often to give advice which will save inventors the
expense of applying for Patents upon inventions which are not new. Circulars of advice sent
free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

VULCAN WIRE ROPEWAY,
 for Conveying ORE, CORDWOOD, ETC.

SNYDERMINE, CAL.

In reply to your inquiry as to how the 'Tramway' is doing, am prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

We can easily transport 65 tons of ore in 10 hours, with two men to load and one to tend brake, and with all the Wood Carriers on, we can transport 14 cords of wood in the same time. When I look back upon the time when I was paying at the rate of \$2.50 per ton for hauling ore, whereas it is now done at the rate of 12 1/2 c. per ton, making a saving of \$150 per day, and also, where it formerly cost me \$5.50 per cord for wood delivered at mill, it now costs me but \$3 per cord, making a saving of \$2.50 per cord—I must say that I feel pretty well over my Tramway investment for it is a PERFECT SUCCESS.

JAMES BARRON, Supt.

VULCAN IRON WORKS,
 135-145 Fremont St., S. F.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the slides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RICH QUARTZ IN VOLCANO DISTRICT.—A *Madro Ledger*, Feb. 23: At the Irma gold mine, near Volcano, they have found another ledge in the shaft at a depth of 175 feet, which is from 12 to 18 inches in width, and prospects very rich in free gold. This vein crosses the Griesbach ledge on the surface down to 40 feet milled \$30 in free gold; from the Griesbach 700 tons yielded \$40,000 without the sulphurets. The ore contains fully 10 per cent of sulphurets, which vary from \$200 to \$800 per ton. By the middle of February a station will be cut on the 200-foot level, and drifts run north and south, when stoping will be commenced and rock taken out to keep 10 stamps going. The Newton Company, which has been prospecting on Jos. Mason's ranch for gold-bearing quartz, after sinking 53 feet on the ledge, are so well satisfied that they will run a tunnel to the shaft. The prospectors are now engaged in perfecting articles of incorporation. The ledge upon which they are working is more than a mile long upon Jos. Mason's land, and he has agreed to deed them 1500 feet whenever they find milling ore in paying quantities. These people are greatly pleased with their prospect, and if they strike the ledge in the tunnel, and it looks as well as it did in the shaft, they will put up a mill. Wm. Love and Emmet Meehan have found a very rich prospect of quartz out near the river.

AMADOR GOLD MINA SOLD.—The sheriff sold the Amador gold mine on an execution issued on a judgment held by J. P. Darling. Mr. Darling bought the property in for the amount of his judgment, the amount of the judgment liens and the expenses making a total of \$7,027.22. This is subject to a redemption in six months.

Butte.

THE CATSKILL MINE.—*Matysville Democrat*: On Saturday last the Catskill Mining Company, of Bangor, made its usual weekly cleanup, and realized for the week's run about \$1000. They are not running their arrastres regularly on account of having to use green wood in the furnace, in consequence of which half-time only can be put in. When we consider the fact that only a part of the week was really worked, the cleanup was a very large one.

Calaveras.

MURPHY'S.—*Calaveras Citizen*, Feb. 4: At the Norfolk, a large number of miners are now at work on the gravel-bed lying east and in close proximity to the quartz vein. The gravel is rich, and a good cleanup is looked for. A successful run has just been concluded in the Campbell mine, on Indian creek, from quartz selected from the dump of the Washington mine. The cleanup was very satisfactory. Caesar Corporandy & Co. have opened up a fine body of auriferous gravel in their mine on quartz gulch, adjacent to town, near the old "Salts and Senna" claim, worked some years ago by Dr. Jones & Co. The bonding of Blood's mine, the old Collier property, will again draw attention to this much-neglected district. Quartz of exceeding richness has been taken out of this mine in time gone by. The advantages of developing a good mine there is great. The mill and the mine of the Beatrice Co. is all that is claimed for it. The mill is running smoothly, and stoping in the lower levels opening up new riches. The few miners at work find no difficulty in keeping the mill constantly running. The ore-body is large and easy of extraction. Five more stamps are to be added at once; preparatory work is being done now to place the battery in position. The past week brought no incident of interest other than the visit of several mining and mill men to our town to further the end in view of owners to perfect operations in some of our mills, and to complete arrangements to start developments in mining properly in several mines of known repute. That our mines are coming into notice is evidenced by the fact that inquiry is almost daily made about them. Supervisor McCormick and his partner, W. A. Bisbee, were in town last week. They, in connection with Wm. Thomas, were engaged the past 12 months in running a tunnel to tap their gravel mine on Central Hill. Hard slate has been encountered, and to accelerate work they have under consideration the placing of a Burleigh drill in the tunnel. Over 1100 feet have been run. There is still some 600 feet yet to run to strike pay gravel.

Humboldt.

WILLOW CREEK.—*Cor. Blue Lake Advocate*, Feb. 4: There has been a good deal of snow in the Willow creek section this winter so far, but it has been not a little cut down by the rains, which have been heavy, until at this writing there is none of the "beautiful" in sight excepting, of course, on the distant mountains. Messrs. Getchell, Little and White have combined to work the Getchell claim this winter. So far as operations have gone, prospects are fine. John Haney, owner of the Haney claim, is meeting with his usual success. Anybody who has ever lived on the creek knows what that means. John S. Kelly is hammering away on his mine. Other claims are being worked, the Cora and the Curran being among the number. However, as might be expected, the high water has retarded operations along the creek somewhat. It is a significant fact that the assessment work on all the claims has been so promptly attended to. This is one of the many evidences that might be adduced of the confidence in the future of the Willow creek mines.

Sons Eureka parties have lately become interested in certain Three creek mining properties. These properties are to receive attention the coming spring. The general outlook here may be characterized as good. There is no burrah, but a quiet, persistent industry which tells in the long run. All mines equally well worked are panning out equally well. A good deal of prospecting will be done in this locality the coming season. The attention of many prominent mining-men is being drawn to this district, all of which augurs well for its future.

El Dorado.

FRENCH HILL.—*Georgetown Gazette*, Feb. 2: Development work on the French Hill quartz mine, between Spanish Dry Diggings and the river, has been progressing for the past two months under a Sacramento company. The tunnel is now in 75 feet. Six men are employed. This is one of the rich producing mines of earlier days, which has been lying idle.

BEAR CREEK.—*Georgetown Gazette*, Feb. 2: H. Wagner has bonded his seam mine on Gold Hill to G. W. Cummings. This is undoubtedly a good mine, and in all probability will be a sale. O. S. Grover has got his gravel mine on Bear creek in good running order, and soon expects to be washing out nuggets. Mr. Robinson of Mrsquito has been in the vicinity of Georgetown for the past week looking at the mines. He seems to be very favorably impressed with that locality, and thinks of locating there.

Kern.

THE ASPHALT MINES.—*Bakersfield Californian*, Feb. 4: Regular trains began running on Thursday, and matters at Asphalt are now assuming a very lively air. A number of buildings dot the place to house the men engaged in mining asphalt and drilling for oil. The poof and boom of the blasting go merrily on every day, and large quantities of asphalt are being piled up. The extent of the deposit thus unearthed is making the hearts of the company's officials glad, and astonishes the visitors who already appear to be "spying out the land." The first train on Thursday carried a good load of passengers. The company, encouraged by the output and development, have expert builders on the ground, and the plant and kettles for refining are being erected with a view to the handling of large amounts of asphalt with the utmost economy in time and labor. Loading chutes, kettles, tracks and dumpers are all arranged with a view to these ends. The railroad has already established cattle corrals, turntable, etc., and will no doubt soon require an agent to care for the large freight business, besides that of the asphalt company, which is already finding its way to Asphalt as a shipping-point from the Carissa plains and the hundreds of square miles north, south and west which are now brought near to this station, and are dotted with cattle and sheep men and ranchers and homesteaders. We understand funds have already been subscribed in Bakersfield to build a good wagonroad to the country westward, tapping a territory heretofore tributary to San Luis Obispo. This is a business-like proposition. The railroad built more wisely than they knew in reaching simply after the extensive asphalt deposits as their objective point for the new branch.

Nevada.

GOOD CLEANUP.—*Grass Valley Telegraph*, Feb. 4: The mill at the Pennsylvania mine has been running of late and on good ore. There were 16 tons (not loads) put through the mill recently, and it paid about \$25 per ton, not counting sulphurets. It is reported that the Pennsylvania has a little bonanza out there.

THE GOLD FLAT MINE.—*Grass Valley Telegraph*, Feb. 1: We have a piece of ore from the Gold Flat mine which is excellent in quality as milling ore. The mine is situated just the other side of the Town Talk and is near the Narrow Gauge railroad track. We had a conversation with Mr. Bennett May, who knows all about the property, and he regards it as the best prospect for a mine that there is in that portion of the county. Mr. May thinks that there are three chutes of ore in the mine, the first being 75 feet in length and averaging 15 inches in thickness, the second being 100 feet in length and varying in size from six inches to two feet, and the third being 250 feet in length and varying from three feet to one foot in width. The ledge in the drift is now 20 inches wide and in good ore. A mill on the property would soon crush out gold enough to pay dividends. More than one excellent miner is of the same opinion.

Sierra.

THE ORIENT MINE.—*Mt. Messenger*, Feb. 4: The main tunnel of the Orient Gravel Mining Company has now reached a point within about 30 feet of the bottom of the shaft which was sunk to the channel several years ago. The tunnel, if we remember correctly, is something over a thousand feet long, and all of it is through hard rock. This is the second tunnel run, the first being 80 feet too high. To push the second tunnel to completion has been an arduous undertaking. John German and son of San Juan are largely interested, and have the greatest faith in the ultimate success of the claim. The shaft above noted was sunk several years ago, and from drifts run from the bottom an excellent prospect in coarse gold was obtained. The new tunnel strikes the channel somewhat lower than the bottom of the shaft, and will thoroughly drain the channel which it taps at the western or down-stream end. Persons familiar with this section where the claims are, have no doubt of there being a large channel in the ridge, as Indian creek, one of the richest creeks in the mountains, was fed from the ridge under which the Orient claims lie. The locations follow the trend somewhere in the vicinity of "Nigger Tent." Nearly, if not quite all, the owners of this property live at

San Juan and vicinity, and deserve all the good luck which seems in store for them.

Siskiyou.

GRAVEL.—*Yreka Journal*, Feb. 8: Lee, Lash & Co. are still getting out good pay from their blue gravel claim on Greenhorn, about a mile south of Yreka. They are running a tunnel along the old channel at a depth of over 100 feet below the surface, and expect to take out considerable gold this season, by having a first-class pump to afford good drainage. The blue gravel in which the gold is found is evidently the channel of a large stream of the prehistoric times, or possibly a large lake. The development of this claim will also be the means of ascertaining the true course of the channel, which is believed to extend from the Siskiyou mountains to and through Yreka basin, and thence southward to the Sacramento valley. A great amount of snow has been piled up on the mountains surrounding, during the continued storms prevailing most of last week, which will be of great benefit to miners in the spring and summer months. The weather has been so cold, however, since the storms ceased that the water supply is frozen so as to prevent any mining at present, except in drifts and tunnels, especially in the high altitudes.

QUARTZ VALLEY.—*Yreka Union*, Feb. 4: Active preparations are being made to start up in full blast mining operations in the Quartz Valley district in a few days.

Trinity.

THE TRINITY RIVER MINES.—*Cor. Trinity Journal*, Feb. 21: There are more hydraulic mines working in the vicinity of Junction City than the people outside of the county are aware of. In all probability there is no other mining town in California where that class of mining can be pursued without interference—certainly not within the knowledge of the writer, who has made frequent visits to nearly every mining camp in the State. Commencing at the Evans' Bar claims of H. H. Carr & Sons, on the east side of the river, we cross the river to the claim now being worked by a large company of Chinamen, from whom it is almost impossible to obtain any information. After leaving that claim, we go to the Last Chance claim, belonging to Ham & Marsh, then to Chapman & Fisher's and Mrs. R. Gribble's, after which we cross to the east side of the river to the Good Friday mine, then to the Sheridan Bros., then to the Haas mine, opposite which are the old Sturdivant and Pickett claims, the latter of which is part of the Hayes' property; then down a mile farther, on the same side of the river, to the Hayes' gravel mines, where six giants and 30 or more men are employed. Owing to the fact that piping operations had not commenced on this property at the time of our visit, we concluded to wait until our return from the lower Trinity, at which time they will probably be washing under full pressure. Continuing on down past the Hocker property, we reach the David Evans' claim of 95 acres, now being worked by Messrs. Begel and Day. The water is carried to the claim by a mile and a half ditch from Canyon creek. Two giants are in use with four and five inch nozzles and about 400 inches of water, with a pressure of about 80 feet. For many years this has been a good paying claim. We next reach the Jacob's mine (drift and hydraulic), which we propose to visit on our return to Junction City. Then last, but not by any means the least, we reach the Lorenzo & Leibbrandt property, which is the last of the mines now being worked between Junction City and North Fork. This magnificent property consists of 882 acres, lying on both sides of the river and about four miles below Junction City. This property has been worked steadily since 1853, and by its present owners since 1872. Many hundreds of thousands of dollars have been produced, and we are informed that it still pays well. At the time of our visit 13 men were employed. About two acres of ground are worked off each season, and the bedrock is about the roughest the writer has ever seen. There are deep depressions in it many feet in depth, and in some places it must have been very difficult to work. There must be at least a half-mile of bedrock uncovered, a great deal of which has never been cleaned up. The McGillivray ditch, ten miles long, brings the water from Canyon creek. This ditch has a capacity of 3000 inches; there are four other ditches each about a mile long. There are about 4000 feet of pipe from 8 to 22 inches in diameter on the property. There are many acres of gravel in high benches all along the river between Douglas City and North Fork awaiting the advent of capital to bring water to them.

NEVADA.

Washoe District.

CON. CAL' & VA. MINE.—*Virginia Chronicle*, Feb. 4: 1500 level—We continue running water through the old stopes at different points, and continue the extraction of ore and fillings in working upward from the sill floor in the old stopes. 1600 level—Are repairing the main south drift and the east crosscut leading therefrom to the npraise connection with the 1500 level north drift. 1650 level—Have continued making necessary repairs to the drifts on the sill floor of this level. We continue to extract some ore from the old stopes, eight floors up in the npraise, No. 6 carried up from the main north-west drift; also from the old stopes in working north from the crosscut run west from the north-west drift. Have extracted during the week from the 1500 level stopes and 1650 north-west drift openings and raised to the surface 389 cars of ore about 389 tons; average assay value of which, per mine car samples, is \$30.63 per ton. Shipped to Morgan mill 359 400-2000 tons of ore. Average assay value, per railroad car samples, \$31.05 per ton. The Morgan mill commenced to work this ore to-day.

OPHIR.—1465 level—The npraise started on the

sill floor, on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground, 101 feet below the sill floor of this level, has been carried up 3 feet; total height, 99 feet; and connected with the north lateral drift on this, the 1465 level. At the point of connection we are cutting out a chamber in which to place an engine for the purpose of hoisting and lowering cages through the npraise.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 18 feet; total length, 515 feet, and is in a softer vein porphyry formation.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 26 feet; total length, 646 feet; face in porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 21 feet; total distance west of the joint shaft, 2838 feet; face in hard porphyry.

UNION CON.—900 level—The joint Union Con. and Sierra Nevada west drift has been extended during the past week 21 feet, making the total distance west of shaft, 2838 feet. The face is in hard porphyry.

CHOLLAR.—The north drift from the south line, 550 level, is out 137 feet; face shows bunches of fair-grade ore. The east crosscut from the north drift, from east crosscut 160 feet south of north line, 930 level, is out 50 feet; face in porphyry. Are retimbering the two north compartments of the main shaft above 930 level.

POTOSI.—The east crosscut opposite the Potosi winze, 930 level, is out 289 feet; face in porphyry. Have started a drift south from this crosscut, at a point 30 feet back from the face, which shows streaks of quartz; the drift is now out 10 feet. South drift from top of raise, 1000 level, is out 98 feet; face in porphyry and low-grade quartz. The north drift from top of raise, 1000 level, is out 50 feet; the whole face is in quartz, car samples from which average \$20 to \$25. Have commenced grading the north-west drift, 1800 level, Ward shaft, and are now timbering the station at bottom of Potosi winze. Extracted and sent to the mill the past week 441 tons of ore from the 550, 930 and 1150 levels. Milled during the week 441 tons; on hand at mill, 80 tons and 1250 pounds. Average battery assays, \$23.56. Average car sample assays, \$27.07. Shipped to U. S. Mint, Carson, 440 pounds crude bullion.

BULLION.—The east crosscut, 100 feet north of top of raise from east crosscut, 320 feet south of north line, 1300 level, is out 75 feet; face is in porphyry and quartz. The west crosscut from the north-west drift, 300 feet south of north line, 1800 level of Ward shaft, is out 240 feet; face in low-grade quartz and porphyry.

ARAX.—During past week have been running the north tunnel in a northerly direction, parallel with the ledge. This tunnel is to be run into the Daniel Webster, from which point the company will run crosscuts and sink winzes to expose the mineral belts of both these mines.

WARD SHAFT.—Have completed putting in the pressure pipe to the 1800 level, and are now making connection from it to our blowers. The west crosscut from the north-west drift, 300 feet south of north line, 1800 level of the Ward shaft, is out 240 feet; face in low-grade quartz and porphyry. Have completed grading the north-west drift, 1800 level, and are now timbering the station at the bottom of the Potosi winze.

EXCHEQUEA.—Have completed putting in the pressure pipe to the 1800 level of the Ward shaft, and are now making connection from it to our blowers.

ALPHA.—Have completed putting in pressure pipe to the 1800 level of the Ward shaft, and are now making connection from it to our blowers.

NEW YORK.—We ceased shipping ore to the Washoe mill on the 30th of January, our contract with the mill having expired. Will ship to a river mill as soon as the roads will permit. Have resumed sinking the incline winze below the 650 level. The repairs to the southwest drift from the shaft, 850 level, are completed. The west crosscut from the southwest drift from the shaft, 850 level, is out 21 feet; face is in clay and porphyry. Shipped to the Washoe mill during the past week 131 tons, 1172 pounds of ore; milled during the week 191 tons, 1174 pounds of ore; on hand at mill, none; average battery assays, \$32.70; average car sample assays, \$38.10. Shipped to U. S. Mint, Carson, 437 pounds of crude bullion.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 6 feet, through hard porphyry and small seams of quartz; total distance from north line, 42 feet.

KENTUCK.—We continue to extract about 2 tons of ore per day from the stopes above the east crosscut on the 160 level. Have commenced to open the 1100 level through the Jacket shaft.

UTAH.—340 level—The south drift from the main west drift at a point 595 feet in from the shaft has been extended 23 feet; total length, 64 feet; continuing in vein porphyry and clay formation. No decrease in the flow of water from the face of west crosscut No. 3.

BEST & BELCHER.—200 level—At a point in north drift, 17 feet in, we have started a west crosscut, No. 1, and extended same 18 feet during past week, passing through clay and bunches of quartz. 900 level—West crosscut No. 3, started from top of npraise No. 1, from 1000 level, has been advanced 12 feet; total length, 119 feet; face in soft porphyry. Also did some repairing during the week.

OCCIDENTAL.—The main north drift, 750 level, has been extended 17 feet; total distance

from No. 1 winze station, 640 feet; face is in quartz with streaks of pay ore. No. 2 winze from south drift, 750 feet, is down 50 feet; bottom in low-grade ore. The Zedig drift, Sntro tunnel level, has been extended 25 feet; total length of main drift, 805 feet; face in hard porphyry.

ANDES.—On 420 level north drift from east crosscut No. 1, north, was advanced 18 feet; total, 81 feet; formation, quartz.

GOULN & CURRY.—200 level: During the past week, west crosscut No. 5, started 432 feet from main west drift, has been advanced 8 feet, passing through hard porphyry; total length, 278 feet. On the Sntro tunnel level the joint north drift with the Savage Co. has been extended 14 feet; total length, 872 feet; face of drift in hard porphyry. We still have about 11 feet to go before we reach our south boundary line.

HALE & NOECROSS.—We continue retimbering main shaft above the 500 level. Main Incline—Are making the necessary repairs. 1400 level—Have started to retimber the main north drift on this level. 1800 level—Have been making repairs to main north drift the past week. West crosscut No. 1 from the main south drift was advanced 20 feet; total length, 95 feet; face in porphyry. No. 3 west crosscut from main north drift was advanced 18 feet; total length, 290 feet; face in porphyry. West crosscut No. 4 from main north drift was advanced 17 feet; total length, 139 feet; face in porphyry with seams of quartz.

Ely District.

GOON ORE.—Speaking of several lots of ore treated by Prof. Garvin, superintendent of the Gervase-Brown electric mill, the Salt Lake Journal of Jan. 26th says: "Another lot from Ely, White Pine county, Nevada, running 4½ ounces gold, was roasted five minutes with five per cent salt, and leached 12 hours, saving all but a trace. Mr. Frank, who brought in the ore, was there when the test was made, and took his own samples. Prof. Garvin is known all over the West as a conservative and reliable metallurgist, and his statements can be implicitly believed." The ore referred to above was shipped from the Jona mine two weeks ago by H. H. Brown, of Helena, Montana, who has been taking ore from all parts of the mine for a month past.

Ferguson District.

DULL.—White Pine News, Feb. 4: Lew Carpenter and W. J. Peters, who left for Ferguson district two months ago, returned Sunday last. They report everything down that way dull in the extreme.

Osceola District.

LOCATIONS.—White Pine News, Feb. 4: More location notices have been received from Osceola this year at the recorder's office than from the rest of the county combined.

ARIZONA.

NO BOTTOM YET.—Tomhstone Epitaph, Feb. 5: The shaft at the corner of Fremont and Seventh street, being put down by T. M. & M. Co., has reached a depth of 80 feet, and 15 feet below this point the diamond drill has penetrated without striking solid formation. How far the shaft will have to be sunk before drilling ground is reached is an unfathomable mystery. The depth of loose ground at this point has been a source of surprise to old mining men, who predicted that bedrock would be encountered in from 30 to 50 feet. It would not be a surprise now if a depth of 150 feet would fail to get through what now seems to be a deep gorge filled with sediment from the adjacent mountains. Until this is reached, no attempt will be made to renew operations with the drill.

ORO BLANCO MINES.—Citizen, Feb. 4: Geo. W. Cheyney, speaking of his mining property at Oro Blanco, said everything was in splendid shape, and there was an unlimited supply of fine mineral, and the only drawback was a scarcity of water. His men are operating four large hand-jigs, and are compelled to have them so placed that the water which has been used in an upper jig can be run off and saved for the next below, and so on down. He has even had to pack water on burros and have it brought up the hill for operating purposes. C. W. Kempton, superintendent of the Ansterlitz Mining Company, had, he said, lately sunk a new shaft to a depth of 130 feet, which would be used as a working-shaft as well as for water, the flow of which was surely increasing. The Ansterlitz mill is about finished and ready to start.

IDAHO.

ON A COMPREHENSIVE PLAN.—DeLamar Nugget, Feb. 4: An important deal has been about consummated which will in a very few days start work on an extensive and comprehensive plan on the group of mines on DeLamar mountain, popularly known as the Lepley group, comprising the Chatanqua, Manhattan, Howe-Manhattan, Beck and three other claims, and fractional claims, all located in one compact group on the summit of the mountain, next west of and adjoining the DeLamar mines. All of these properties are located just where one traveling about the mountain would naturally locate the center of the greatest mineral deposits. Considerable work has been done upon them but no depth has been reached, and as the ground near the surface is considerably broken and misplaced, although large bodies of ore have been found the walls of the ledges have not been defined. When depth has been reached, there is scarcely a shadow of a doubt but what the group will prove to be an immensely valuable property. We are not fully informed as to the particulars of the deal, but understand that Wisconsin capitalists—among them are expert miners—have secured a working bond upon the properties for a considerable length of time, for which they are to begin work in a very few days and continue it with a large force of men during the term of their

option. Messrs. Lepley, Davies, Kent, Smith, Howe and others, all citizens of DeLamar and Silver City, are the owners of these valuable properties. We hope the capitalists who are now going to exploit them have the nerve to sink a deep shaft at some favorable point on the property. We have seen enough shallow tunneling done on our grand old hillion-producing mountain to convince the *Nugget* expert that that is not good mining. The new hoisting works, now completed on the DeLamar Company's property, are constructed for the purpose of sinking a shaft from the surface down to the mill-tunnel level. The tunnel starts in just above the level of the ore house of the present mill, and, when completed, will cut the vein series 482 feet vertically below the Wahl tunnel and 1100 feet under the summit. Eventually ore will be delivered at the mills by track in this tunnel, which will reach the first of the series of veins at a distance of 3600 feet. This is laying out work which it will take years to complete, but will make the mine development very complete as low as the creek level. It is seldom that a whole group of mines can be worked to such a depth without employing hoisting machinery.

BRITISH COLUMBIA.

SHIPPING ORE PAYS.—Nelson Miner, Feb. 3: To say that the Slokan district is rich is a waste of breath. Every one knows it by this time, but the following figures may be interesting, being based, as they are, upon no mere assay, but being the result of a shipment of over 300 tons of ore taken from the Freddie Lee. To simplify matters, we have taken an average of the total shipment, and treated it as one ton. The smelter returns show that the 300 tons averaged 70 per cent lead, consequently each ton of ore contained 1400 pounds of lead. Deduct 70 pounds from this for waste, and we have 1330 pounds, valued, say, at .0385 cents per pound, or \$51.20 per ton. In addition to this, each ton, on an average, was found to contain 125 ounces of silver, which, being valued at 80 cents per ounce, means \$100. The total value, then, of a ton of this ore is \$151.20. With thousands of tons of such ore as this in sight, a man might well be justified in thinking his fortune was made, but, unfortunately, he has to consider the means of getting his mine to the smelter, and it costs something to do this. The figures below show what the actual cost of transferring ore from the Slokan to Tacoma has been, by existing freight routes:

	Per ton.
Mining and sacking.....	\$10
Freight to Kaslo.....	40
Kaslo to Tacoma, via Nelson.....	15
Duty, 1½ cts. per lb. on 1400 lbs.....	21
Smelting and refining and freight of hillion to New York.....	22
Sacks.....	2
Office expenses.....	1
Total.....	\$111

These figures form a monument testifying to Mr. Wardner's pluck, which will last long after the Freddie Lee has been worked out. This shipment has only been an experiment, and when it comes down to real business and the mine is turning out 50 tons per day, as it will be doing in six months time, the cost of shipments will be considerably modified. It is calculated that the total cost of shipping to the smelter and treating a ton will be \$38, made up as follows, and, mind you, these figures are not imaginary estimates, but are actual rates offered by the transportation and smelting companies:

	Per ton.
Mining and sacking.....	\$ 5 00
Freight to Kaslo.....	7 00
To Tacoma, via Great Northern or Nelson & Fort Sheppard.....	7 50
Smelting, refining, etc.....	16 00
Sacks.....	2 00
Office expenses.....	50
Total.....	\$38 00

The duty on lead is not included in this calculation, as it is considered that by the time these come into force this tax will have been abolished. Taking these figures as a basis on which to work, mine-owners in the Slokan district can spend pleasant evenings in reckoning what they will be worth in a year's time. Fifty tons of ore per day, yielding \$113.20 profit per ton, will result in a year of 300 working days in the sum of \$1,698,000—a very pretty income for a mine that will not, when this sum shall have been earned, have been discovered for two and a half years; and when one considers that it is not one mine alone that can do this, but practically dozens, one begins to feel a confidence and belief in the future of the country which no temporary or local depression can shake.

MONTANA.

BOULDER DISTRICT.—Phillipsburg Mail, Feb. 2: An activity in mining matters prevails in Boulder mining district, notwithstanding the severe winter, which angers well for the future of the camp. Israel Clem and associates are developing the Eureka and an adjoining lode and taking out good ore. Morgan Johns, R. S. Leveridge, Mr. Maywood and Frank Lang are running a crosscut tunnel on the Jim Purtle lode, now famous for the high assay of its ores at discovery, which is the objective point of the crosscut. The tunnel when under discovery will be 175 feet long and the apex of the lode at that point will be 150 feet above the tunnel level. Peter F. Scherr, Charles Kadell, John Scherr and Christ Larson are running a 300-foot crosscut tunnel on their Bloomington lode, 2000 feet west of the Royal gold mine. The Bloomington tunnel is now in 125 feet, and has already crosscut three ledges, some of which give good prospects in the pan. Mr. Campbell and associates are also wintering on the Royal

gold mountain, developing their claim. In this case, cannot give particulars. The Royal Gold and Silver Mining Co. has some 500 feet of tunnel work let out by contract. The Mount Powell Mining Co. has something over 1000 feet of tunnel work let out by contract on two levels—the lower and the upper. Besides, the company is extending the middle tunnel and sinking winzes from its level by days' work. Rombauer & Johnson are wintering upon the Meta lode and Irving in the tunnel. They have a strong lode to work upon with high-grade ore in a winze below the tunnel level, which assays in gold, silver, copper and lead and very fine-looking quartz in the face of the tunnel.

NEW MEXICO.

COAL.—Silver City Sentinel, Feb. 4: It is reported that the Silver City and Northern Railroad will be extended to the coalfields between this place and Gallup this year. Work will be commenced within a few weeks, and as soon as the road reaches the coalfields the company will put large smelters at work reducing the iron ores at Hanover. If the plan for getting cheap fuel to the camp proves successful, it is quite certain that the Mineral Point Zinc Co. will erect large works at or near Hanover, for the treatment of zinc ore. There are large bodies of zinc ore which would pay for mining and treatment at works in the camp, but which would not pay to ship to Wisconsin for treatment at the company's works there. With cheap fuel at Hanover, the great copper mines of the Santa Rita Copper and Iron Co. could be worked on a very extensive scale. If the deposits of coal near Gallup are as extensive as they are reported to be, and the coal can be delivered at Hanover at such rates as have been figured on, it will take but a few months to make Hanover the most important mining and smelting center in New Mexico. Iron, copper and zinc ores are found in abundance at and around Hanover, and it is but a few miles to important silver and lead mines, which would become large producers if the ore produced could be smelted near the mines and at a low rate. A large smelting plant at Hanover would have the advantage of having an abundant supply of lime and iron at hand, while the smelters at El Paso and Socorro are obliged to come to Hanover for their iron, and can get fuel no cheaper than it could be brought to Hanover from the Gallup fields over the proposed railroad. The Brockman mill at Lone Mountain is running steadily on ore from the Brockman mine, which is producing ore in large quantities. The mill is doing better work than it did some time since. There is practically nothing at all doing in the mines at Georgetown. Lessees who were operating in the Mimbre Consolidated Co.'s mines have given up their leases and the outlook for the camp this year is anything but encouraging.

SOUTH DAKOTA.

OPERATIONS SUSPENDED.—Deadwood Pioneer, Feb. 3: The announcement, received in this city yesterday, that the Harney Peak Tin Company had suspended all operations, in both mine and mill, created considerable of a stir. Investigation proved the report correct, and the fact that the men were being paid off yesterday would seem to signify that the shutdown was meant to be of extended duration. No cause for this sudden and very unexpected move is assigned, although various solutions are volunteered. About all that is known outside of the management is that Superintendent Childs left for the East, ostensibly for New York, but returned to Hill City Wednesday, after an absence of but a few days, and that evening ordered that all operations cease. The number of men thrown out of employment is said to be upward of 400. This sudden change in the policy of the Harney Peak people is all the more confounding on account of recent reported rich strikes in the Tenderfoot and other mines of the company, and of the late heavy expenditure in mill improvements and approval and acceptance of such additions to their property. Some insinuate that the company has got tired spending money on barren property, but there are many who believe there is plenty of tin ore in the Harney Peak mines, and that the shutdown is attributable to internal differences in the corporation. One old and well-informed mine operator gave last evening as his opinion that the English stockholders had got tired putting up money for the New York stockholders to spend. It is a well known fact that there has been a strong difference of opinion between the English and American stockholders concerning the operation of the property. The former desired to place the operations under experienced Cornwall tin miners, but to this the New York stockholders objected, and it is not improbable this difference may have led up to the present suspension. In any event, all operations have been indefinitely suspended, and we are hardly prepared to accept as the correct cause of the suspension a telephonic statement that the company is about to put in new fire boxes.

UTAH.

THE SAN JUAN COUNTRY.—Denver Sun, Jan. 30: Cy Warman, the conductor of the New York Sun party, returned Sunday from the San Juan. He said this morning to a Times reporter: "I went clear through to the San Juan and spent two days there, and, as I believe, was the only newspaper man who went in that far. The other party who furnished matter for the press did business from Bluff City, a little Mormon town 100 miles from the placer mines. Of course there is gold in the San Juan, in the river and on the hill tops. There is gold anywhere and everywhere in southern Utah. But it seems to me that in the place of this excitement colors are fewer and farther between than at any other place in that section of the country. On my way over I heard of gold placer properties on the Colorado, and on my return I spent ten days panning and prospecting

on that stream. We took a boat and went down the river from Crescent creek or North Wash, a distance of about 50 miles. At Good Hope we spent two days, and in all the panning we never failed to get a color. The gold is coarser on the Colorado river, and is worth \$20 an ounce at the express office. At California Bar we found two men working a Kent placer machine. They cleaned up after running yards of dirt and got \$10 worth of dust, which we brought home with us. These men say they make from \$5 to \$8 per day of ten hours, handling the dirt twice. At this point Salt Lake people are aiming now to put in machinery, and the teams that brought us out will take back material for the Salt Lake men. The Henry mountains are a good mining district, a purely gold district, having both ledge and placer mines. I believe that during the coming summer there will be a great deal of prospecting in the Henry mountains and along the Colorado river; and that some good will come from the San Juan hoom, after all. I believe, too, that the men who persist in an attempt to keep up the fake boom on the San Juan will work a great injury to the rest. As to nuggets, there are few or none, the richest one, in one of the richest bars of the Colorado river, being worth less than \$1. There is lots of flake gold, and the poorest pan ore had in all our prospecting contained 40 colors, and we must have lost many others because of our inexperience. Indeed, the biggest pan we had contained about 150 colors. There are good wagon roads from Green river clear through to San Juan, 174 miles, so that machinery can be taken to any point along the route without trouble. The distance, however, to the Colorado river is only 10½ miles. If a man puts in \$25,000 at one of the large bars of the Colorado he can thresh out \$1,000,000. I heard from a reliable trapper, who has lived on the Colorado river six years, of very rich hare farther down; some below even the mouth of the San Juan. This same trapper spent 22 days on a low bar washing with no machinery except a pickle keg, and he washed out \$80. The low bars appear to be the richest, but they can only be worked in low water. And as low water lasts eight months, this country is a better place to work than some places farther north, which are frozen up seven months in the year. I believe that any man who understands washing gold can make good wages on the Colorado. But that is not the way to do it. What that community wants is capital. It wants improved machinery to wash out the ground. That is all there is to do; there is no question as to the existence of gold on that river. The same old trapper as above mentioned told me two years ago that he prospected on a tributary of the San Juan over in the reservation, and found placers worth \$3 a yard. But the Indians would not allow white prospectors on the reservation, or that strip of country recently opened up, which I understand never was a part of the Navajo reservation proper. The Indians were simply allowed to use this strip, which extends from the San Juan back 20 miles, and which lies directly opposite the scene of this last excitement, for watering purposes.

NEW PLANT.—Park Record, Feb. 4: Last week the Record published an article in reference to the Daly West, in which it stated that it had learned on good authority that the owners of that property had ordered a new hoisting plant like that of the Silver King, and would build a mill during the coming summer. This week the Record is enabled to tell its readers that the information is entirely correct. There is no longer any doubt of the richness of the Daly West, and next summer will see it join the ranks of the Park's big producers. The ore reserves uncovered are beyond the most sanguine expectations of its owners; and when it is stated that they are highly elated, only a dim idea of their pleasure is conveyed. The Record is pleased to note this verification of the faith exhibited by Mr. Daly and associates, and of the judgment of the host of miners who have always maintained that the Daly West was a big mine and that a deep shaft would certainly uncover a large body of rich ore. When it is considered that a large three-compartment shaft was sunk on this property a depth of 1200 feet at a cost of not less than \$50,000, to say nothing of the expense of moving and placing machinery and erecting buildings, our readers will understand why Mr. Daly and associates feel rather comfortable over the outcome and at the same time get an idea of what the difficulties are to open up a mine and get down to the ore before there is any possibility of any return. Even under the favorable conditions which have always surrounded this property, great chances were taken in the investment of that amount of capital, for the vein might have been barren at the point where it was intersected and remained so through the whole length of the property. At this writing it is not known just where the new mill will be built, what its dimensions will be, nor when work will be commenced; but the writer has positive information to the effect that the work will be done, and done during the coming summer.

FROM SAN JUAN.—Ferguson Lode, Jan. 30: J. J. Jennings arrived here direct from the San Juan country last Friday and will proceed down the country to Yellow Pine district. He says the new goldfields are a fake. The snow is deep, everything is sold at high prices, and travel is only possible over the rough mountain country with burros. Freight is three cents a pound from the nearest shipping point, and hundreds of idle men without a dollar are anxiously awaiting a chance to get out. The small amount of gold already discovered is on benches above the river and will require heavy machinery to operate or work the ground. He says the reports of mineral existing in the Henry mountains is well founded, and it is the firm belief of many prospectors that they will be the objective point when spring opens up.

Market Reports.

Financial and Commercial Review.

SAN FRANCISCO, Feb. 9, 1893.

The uniformity of prices of silver during the week just past has been its most notable feature. There was no change either in New York or London for three days, and the fluctuations since then have been very slight. As the time set for the reconvening of the monetary conference approaches there is renewed interest in its probable action. There was for a time fear that the conference would not convene at all, but the rumor, if there ever was any, seems to have passed. The nations participating in the conference are, most of them, anxious for some settlement of the question, and the unsatisfactory result of the previous conference has by no means been taken as an indication that no definite conclusion can be reached. Senator Jones, back from Europe, says England is the chief obstacle in the way of bimetalism—a statement, by the way, that is not altogether original or unexpected. But, nevertheless, there is a strong silver sentiment in England, and that nation will be compelled, in deference to public opinion, to share in the conference of nations on the subject.

THE METALS.—There is nothing to report in the metal market. Eastern advices are that copper is still weak.

Quicksilver Shipments.

The exports of quicksilver from San Francisco in January were as follows:

To—	Flasks.	Value.
New York	2,600	\$104,000
Mexico	375	15,650
Australia	200	8,400
Central America	20	840
New Zealand	12	420
British Columbia	1	40
Totals	3,208	\$129,360

The total for January is the largest for any month in several years, being nearly half as much as exported during the year 1892. In January, 1892, the shipments by sea were 637 flasks, against 379 for the same month in 1891.

The receipts at this port in the past month were 2243 flasks, against 1701 in January, 1892, and 1663 in 1891.

Subtreasury Report.

J. P. Jackson, Assistant Treasurer United States at San Francisco, reports cash on hand January 31, 1892, as follows:

United States notes	\$ 50,607 00
Treasury notes 1890	1,500 00
National Bank notes	18,665 00
Gold certificates	290 00
Silver certificates	172,405 00
Gold coin	26,358,415 50
Standard Silver Dollars	23,658,969 00
Subsidiary Silver coin	4,015,690 00
Minor coin	14,212 98
Total	\$54,290,754 48

Standard Dollars shipped in Jan.	\$31,000 00
Fractional coin shipped in Jan.	29,492 00

Tuesday	38 1/2	38 1/2
Wednesday	38 1/2	38 1/2

The Mining Share Market.

There has been no very encouraging news from the Comstock the past week and no active developments in stocks. It is telegraphed from Denver that J. L. Flood and several other California capitalists are in that city with a view to establish an exchange of business between the Mining Exchange of Denver and that of California. Their plan is to list on the San Francisco Exchange some of the great mining stocks of Colorado, and to list on the Denver Exchange, California and Nevada properties. Those mentioned by the Denver telegram as California stocks are the "Comstock," Virginia City, Ophir,

"Consolidated Comstock and Virginia." That's pretty good! Such is the fame of the Comstocks outside our borders. It shows how Denver mining-stock sharps are posted about our doings. The rest of the dispatch says: "The gentlemen visited the Exchange this morning and were warmly welcomed. They talked of their plan and proposed that to carry it out and secure the benefit of such connection, a special wire be worked between the two Exchanges. This afternoon at a meeting of the Mining Exchange a committee consisting of W. B. Root, W. C. Wynkoop, D. E. Ezekiel, R. H. Buck and W. F. Reinhardt was appointed to meet with the California delegation in their special car at the Union depot this evening and discuss the question. The gentlemen of the California delegation were unanimous in their statements that from what knowledge they had the mining interests of this State are in a very prosperous condition."

I might have up our local market to quote some of the Colorado stocks, but we doubt it. If we know no more of them than they do of ours, there would be some fun in the business anyhow.

The Comstock pay-roll for the month of January amounted to \$126,683.58, showing a decrease over that of December of about \$13,000.

The following shows the standing of the various mines for the past month:

Manufacture of Oil Gas.

A paper by James B. Ball, read before the students connected with the Institution of Civil Engineers, describes the manufacture of oil-gas at the Holladay Works, of the Great Northern Railway Company. Pintsch's system of gas-making is employed, and the works have been designed to produce about 60,000 cubic feet of gas per day. In each retort house, contained in 4 benches are 8 pairs of 10-inch D-shaped retorts, 6 feet in length, made of one-inch metal. The pairs of retorts are placed vertically over one another, and are connected by cast-iron mouth-pieces on the opposite ends to those at which the oil is delivered; doors being provided in the mouth-pieces for cleansing purposes. In each upper retort is placed a small sheet-iron tray about 2 1/2 inches deep. This tray becomes coated with carbon after a short time, and is changed and cleansed once a week, and renewed after about three months' use. Stouter trays made of steel are now being tried, and promise to prove much more durable.

The gaseous vapor generated in the upper retort passes down through the mouth-piece into the lower one, and at the other end through a short vertical pipe into the hydraulic main. The retorts are set in specially-made fire-clay blocks, and on both sides small sight-holes are formed at the furnace end, with the object of ascertaining and regulating the temperature. They are kept as nearly as possible at a cherry-red heat; but the lower one, being immediately over the furnace, is generally at a higher temperature than the upper one; and this extra heat is beneficial in thoroughly gasifying the vapor before it passes into the hydraulic main. Each pair of retorts will make between 600,000 and 700,000 cubic feet of gas before they require to be taken out and renewed, the old retorts being broken up and partly used again for new castings.

At the bottom of the lower retort, immediately before the gas enters the hydraulic main, is a three-fourths inch iron pipe tapped into the retort and provided with a stop-cock, by means of which the color of the gas may be seen, this being the practical test applied to ascertain the quality of the gas, and whether the proper quantity of oil is being admitted into the retorts. Another test for regulating the supply of oil is to drop a small quantity of the tar from the gas main upon a sheet of white paper. Should too much oil be admitted to the retort, a greasy ring will be found around the spot of tar. If the right quantity is being used, no greasy ring will appear. Below the stop-cock, and tapped into the three-fourths-inch pipe, is a one-fourth-inch pipe, which is carried to the wall of the building and attached to an ordinary water-gauge which registers up to a head of 12 inches. Each pair of retorts is provided with a separate gauge, and the working-head, which is usually about 3 1/2 inches in the retorts, can be thereby observed.

The furnaces are situated immediately under the retorts, the bottoms being formed by three 1 1/2-inch round cast-iron fire-bars three feet in length, resting upon three cast-iron cross-bearers. This arrangement permits the fires to be easily cleansed from

clinker and ash, and the fire-bars to be renewed without trouble. Immediately below the fire-bars is an ashpans which is kept full of cold water. The furnaces are arched over with fireclay blocks, upon the flat crown of which the lower retort is seated. Three four-inch by three-inch openings or flues are formed in this arch on each side of the retorts, which are protected by a thin lining of fire-brick to a height of five inches. A clear space of two inches is left between the crown of the lower retort and the bottom of the upper one, which is thus fully exposed to the heat and smoke ascending from the furnace. Two small flues are formed on each side of the upper retort, and a semi-circular arch is turned over at two inches clear of the crown. In the center of this arch an opening ten inches square communicates with a semicircular chamber extending the full length of the retort; and flues are brought over from all of these chambers into a center shaft nine inches square inside and carried up through the roof. The whole structure of the setting is held together by angle-irons at the corners with through bolts. Notwithstanding this, it becomes more or less cracked after a little use, for the working of the retorts produces an expansion of 1 1/4 inches at each end.

When in proper working order, each pair of retorts produces on an average between 300 and 400 cubic feet of gas per hour, and the furnaces consume between 160 pounds and 180 pounds of coke for every 1000 cubic feet of gas produced. The setting to the retorts is arranged so that a minimum of work in pulling down and rebuilding is required when new retorts are inserted.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.
 " " Improved Belt Frue Vanner..... 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l Supt. FRENCH GULCH, Calaveras Co., Cal., Dec. 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been \$60 small mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THE CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable.

PRICE, \$575, f. o. b.

Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge.

THE SAN JACINTO ESTATE—Office of the General Manager. CALIFORNIA, Oct. 30, 1891.

GEO. E. WOODBURY, Esq.—Dear Sir: In reply to yours of the 27th inst., respecting the working and efficiency of the "Woodbury" Concentrator placed in our works by you, I am pleased to inform you that it is giving entire satisfaction, it has a much greater capacity than any other machine, and is doing fully one-third more work, with the concentrates equally clean, as from either of the machines at work here.
 (Copy) Yours faithfully, S. HARRIS, Manager.

THE SAN JACINTO ESTATE, LIMITED—Office of General Representative, P. O. address, South Riverside, San Bernardino County.

CALIFORNIA, February 17th, 1892.
 GEO. E. WOODBURY:—Your letter of inquiry about your concentrator came to hand to due course. Your machine is doing well, the motion is all right, and the machine is giving entire satisfaction. Yours faithfully
 S. HARRIS.

GEO. E. WOODBURY, Man'r, 213 to 219 First St., San Francisco.

The Battle-Ship Oregon.

One of the largest modern ships of war yet attempted by our Government is the battle-ship Oregon, now in course of construction at the Union Iron Works shipyard in this city. This vessel is to have a displacement of 10,000 tons, and her principal dimensions are: Length, 348 feet; breadth, 69 feet 3 inches, and depth, from keelplate to superstructure, 42 feet. She was contracted for under the Naval Construction Act, passed by Congress, June 30, 1890, and is to cost, exclusive of armament, nearly four million dollars. The minimum speed to be maintained for four consecutive hours is to be not less than fifteen knots. The hull is to be of steel, not sheathed. Her framing will be on the bracket system, and she will have a double bottom extending from armor-shelf to armor-shelf, and forward and aft. The armor on her sides, for protecting the water-line, will have a maximum thickness of not less than eighteen inches, with a mean depth of seven feet, and the transverse armor at the ends of the belt-line will not be less than seventeen inches thick. The sides, from armor belt to main deck, will be protected by not less than five inches of steel armor. Coal is to be carried back of this casemate. An armored deck, not less than three inches in thickness, will extend forward and aft from the ends of the armor belt, being curved down on each side to meet the side of the ship below the water-line. Over the side armor belt this steel deck will be not less than two and three-quarters inches in thickness. The Oregon will have an approved water-excluding material equal to woodite or cellulose, fitted along the sides, forward and aft, on the slopes of the three-inch protective deck.

She will be supplied with powerful guns, aggregating in all six hundred and thirty-one tons. They will include four 13-inch breech-loading rifles, weighing sixty tons each, with their mounts, shields and equipments; four 8-inch breech-loading rifles; four 6-inch breech-loading rifles; sixteen 6-pounder rapid-firing guns; six 1-pounder rapid-firing guns, and two Gatlings, with all necessary mounts and shields therefor. It will require 306 tons of ammunition to complete the vessel's fighting outfit.

Her 13-inch guns will be protected by 17 inches of armor. The axes of these guns are to be not less than six feet above the deck, and due regard must be paid to interference of fire and the effects of the blasts of the various guns. The six and eight inch guns will be protected by shields and, in addition, by barbettes or otherwise, carrying four-inch armor for the six-inch guns, and six-inch armor for the eight-inch guns. The ammunition for the eight-inch guns will be supplied through armored tubes.

The Oregon will carry twelve torpedoes. There will be seven above-water torpedo tubes—two forward, one aft,

and two on each side. She will also carry a distilling apparatus, which will supply fresh water; the allowance of of water to be carried is to be enough to last fifteen days, besides water for sanitary purposes. The vessel will have a complete electric light plant. This will be the fifth of the war vessels built at the Union Iron Works, and is the heaviest and most important one. The last one finished—

COMBINED WATER-WHEEL AND DYNAMO. (See page 99.)

the Monterey—went into commission this week at Mare Island.

Cruiser No. 6—the Olympia—is, like the Oregon, in course of construction at the Union Iron Works, and

THE UNITED STATES BATTLE-SHIP OREGON.

is being pushed to completion as rapidly as can be done by the large force employed upon her.

ADVICES from the Coeur d'Alene silver and lead mining district in Shoshone county, Idaho, are that owing to the low price of silver the mines will within a few weeks be compelled to shut down. This action will throw about 2000 men out of employment and will have a disastrous effect upon northern Idaho.

California Iron.

The Jones Creek iron mine, half a mile from Humboldt bay, Humboldt county, has been leased to Eastern parties, who intend to open and prospect the deposit. Should developments justify, a furnace will be put up. The ore is a red hematite. It is sincerely to be hoped that experienced Eastern men have this matter in hand and will make a success of it. We very decidedly need iron here which is not so expensive as that brought thousands of miles by sea or rail. Some of the Shasta county iron ore is being used by the Union Iron Works of this city, and is found satisfactory. An iron mining property on Humboldt bay would have the advantage of sea transportation both for obtaining its fuel and for shipping its products. There are, however, in the same county, on Willow creek, some coal deposits now being opened. If the coal is found to be suitable, it may be used in conjunction with the iron-smelting plant.

That cheaper iron is an actual necessity in California is shown by the petition recently sent by the iron foundry and manufacturers of this city asking for a removal of the tariff on this substance. Most of what we consume here now comes from abroad

and pays duty. Some comes from the East, but high railroad rates make this expensive also.

The deposits of iron ore in Shasta county are very extensive, but there is no good coal near by with which to smelt it. There is coal up on the Pitt river which might be utilized for making gas, but notwithstanding the efforts of the people here, they have been unable to obtain capital to develop the properties and start up a plant. One trouble is, there is only one line of railroad in that section, and there would be no guarantee of continued low freights to this city, which would be the principal point of consumption for the product. There are few people here experienced in working iron mines. It would take Eastern men to make a success of such a project. The Shasta iron itself is of very fine quality and, it may be said, there is practically no limit to the quantity. Either the Humboldt or Shasta deposit, systematically worked on a large scale, would exercise a most important influence on our local manufacturing industries.

IDAHO yielded last year \$7,703,000. Of this the silver amounted to \$2,798,000, lead \$2,575,000, and the balance was gold. This is a decrease of \$1,936,000 from the output of 1891. The decrease is due to the shutting down of many mines in the Coeur d'Alene and Wood River regions.

ALL the principal mines at Tintic, Utah, are closed down, the miners employed having refused to submit to a reduction of wages.

Comment.

The Acting-Assistant Treasurer of the U. S. Sub-Treasury in New York, M. L. Muhleman in figuring up the the amount of gold and silver in the world on the 1st of January, makes the two metals come out even. The aggregate of gold is \$3,900,000,000, and silver exactly the same. India and China have the most silver, \$1,700,000,000, and France the most gold, \$1,000,000,000. The latter country also has the most silver, except India and China combined, the amount being stated at \$700,000,000. The United States is credited with \$650,000,000 in gold and \$590,000,000 in silver. According to these figures, with the two metals, France has in gold and silver \$1,700,000,000, which is exactly the amount India and China have in silver. The United States comes next in order in total amounts of the combined metals, having in fact more of each precious metal than all other countries, except France and India and China. A great deal of the gold seems to be drifting away from this country, however, especially of late. It is interesting to note, as to local conditions in this connection, that some months ago the San Francisco sub-treasury sent \$20,000,000 in gold East, and there is still in this city in that institution \$27,000,000 in gold. The leading commercial banks here have also plenty of coin. The surplus of coin on hand in these banks and that in the savings banks is very large, and rates to borrowers are easy, with every prospect of continuing so. In fact, there is too much unemployed money here for the good of trade, and holders would gladly have some outlet for it.

Senator Langford this week introduced two bills, one to abolish the State Mining Bureau, and the other relating to the division of swamp-land districts. With the latter subject this gentleman should be familiar, since he is from San Joaquin county, but with the Mining Bureau affairs he should have nothing to do. Senator Langford's county has more swamp lands and less mines than any other county in the State. This being the case, the Mining Bureau is of little or no value to him or his constituents, and it would be more graceful, to say the least, for him to leave that institution to the care of those in whose interest it was founded. None of the men from mining counties care very much for the various agricultural institutions and bureaus now maintained by the State, but they do not interfere with them, supposing the agricultural communities know best what they want. Senator Langford might exercise similar discretion and not meddle in a subject which concerns him so little. The Governor himself is of the opinion that the miners' representatives should attend to any changes which may be needed to improve the Mining Bureau—an opinion that the public generally will share.

The legislature is actually considering a proposition for county surveyors to prepare plans and specifications superintend the construction, and repair and maintain all county roads. They are to advise with supervisors as to

bridge construction and repair and be paid by the day instead of by fees. The bill has the endorsement of the Technical Society of the Pacific Coast, and was framed at the convention of county supervisors, who are represented in Sacramento by J. L. Maude of Riverside. The object of course is to do away with the generally incompetent road overseers and put a skilled engineer in charge of such work, taking the supervision out of the hands of supervisors or politicians. It is a move in the right direction but a radical change in the system almost too great to expect. To be sure intelligent expert work would greatly benefit all county roads and be a boon to people all over the State. The adoption of the measure would add to the duties of the county surveyors, but they are permitted to employ skilled deputies to assist them. Road building is a branch of the engineering profession which will be of more importance in the future as the country is thoroughly awakened to the necessity of better roads.

The State University and the Mining Bureau.

We have received a copy of the bill introduced in the Assembly by Mr. Kennedy, who originated the measure Senator Langford fathers in the Senate for abolishing the State Mining Bureau. It provides for a continuance of the Mining Bureau museum in San Francisco as at present, except that it is to be managed by the State University. The museum, library, laboratory and all other property of the Bureau is to be turned over to the University; and the Regents may authorize the Department of Geology and Mineralogy of the University to carry out any investigations in the field or otherwise which may be deemed necessary for the elucidation of the geology and mineralogy of the State.

With the copy of the bill comes also a circular giving the author's reasons for the passage of the bill. In this he speaks of the failure of the Bureau as a practical and scientific institution; its inadequate return for money expended; the impossibility of accomplishing geological and mineralogical results in a Bureau hampered in its appointments and operations by political conditions; duplication of work from year to year; uselessness of maintaining the office of State Mineralogist should no money be appropriated for field work.

Mr. Kennedy states in his circular that the bill does not imply the termination of the work of the Bureau—simply its transfer to the University, where it would be carried on in a more practical and scientific manner in the extensive laboratories. He thinks this would encourage the beginning of a systematic study of the geology and mineralogy of the State. The connection of the fieldwork in geology and mineralogy with the University would give opportunity for advanced students in mining and allied branches to spend their vacations in the study of the geology of the whole State. This would establish a practical school of geology and mining such as has been found useful in other countries.

With all due deference to Mr. Kennedy's opinion, the whole plan seems to us impracticable. The functions of the Mining Bureau and the Department of Geology and Mineralogy of the University are totally different. If it is desired to abolish the entire Bureau, with the exception of the museum collection, the bill will answer the purpose; but no Bureau need be maintained to give advanced University students opportunity to spend their vacations studying geology. They can do that without any Bureau.

The study of geology and mineralogy is of slight moment to a Mining Bureau, while it is important to those attending a University Mining Department. The U. S. Geological Survey can give us all the geology we need. One geologist connected with the bureau will know every practical purpose as far as the money interests are concerned. One skilled mineralogist to determine specimens, is all that is necessary. The way to make a mining bureau useful to the mining public is to make it a bureau of general information. Very few miners ask questions about geology or mineralogy. They want to know however, the best way to work their ores and to utilize their mineral deposits; the commercial value of mineral substances and where to dispose of them; the class of machinery or mechanical appliances best adapted for their needs; comparative merits of processes; the statistics and technology of the mining business, etc.

That the Bureau has in a measure failed to satisfy these requirements must be confessed, but there is no reason why it can not be made to do so. It would be better to rehabilitate it on a proper basis than to abolish it. Turning it over to the university practically abolishes everything connected with it except the museum, and even that could be reduced one-half in size without injury.

The University is not equipped to properly maintain such an institution as this. It has not itself achieved any very remarkable success or become famous in its Mining Department. It never publishes any of the results of its

works for the benefit of California miners. The personal investigations of the Professor of Mining are usually published in New York by an Institute of Mining Engineers, when published at all. There are no bulletins from the Mining Department as there are from the Agricultural Department. Whatever is done at the University is kept at the University; the public knows nothing of it whatever. When the students in the Mining Department pursue an investigation of value, they want to be paid for giving an account of their work to the press.

In order to handle the business of the State Mining Bureau, the force in the Department of Mining of the University would have to be greatly enlarged and a different system pursued. The functions of that department would be changed. The Regents of the institution have no reputation for progressiveness, nor do they seem to be in close touch with the public. As the management of the Mining Bureau would be in their hands under Mr. Kennedy's bill, the mining public would be worse off than they are under present conditions.

We can see no merit whatever in the proposition. It looks more like an absolute attempt to kill the Bureau than to remodel it. The Mining Department of the University is educating the students who attend it, and doing good work in that direction; but when the whole business of a Mining Bureau is thrown on its hands, the department will have more than it can properly care for. There should be a separate institution or none at all.

The Conference Agrees to the Mining Bill.

The main topic of interest to the California mining community just now is the probable fate of the Caminetti hydraulic-mining bill, which has been so long pending. From present appearances the bill will become a law in a few days, with the objectionable penalty clause modified as the miners desired it to be. Senator Berry of Arkansas, a relative of C. P. Berry of this State, was bound up in some kind of a cast-iron promise to permit no change in the bill, and would listen to no argument, so the conference committee could do nothing. It was represented that if C. P. Berry would give his consent, the amendments might prevail and the bill be reported favorably by the conference. Thus one individual—an antidebris representative—blocked a bill for the ostensible rehabilitation of hydraulic mining. When the whole responsibility was thrown upon this man he finally telegraphed to Senator Berry that the valley people had no objection to the addition to the penal clause of the Caminetti bill of the following words: "Directly or indirectly injuring the navigable waters of the United States."

On Wednesday of this week, the conference committee came to an agreement, and the Senate bill was amended. Senator Berry received another telegram from his cousin advising him to agree to the proposed amendments, so there was no more opposition. The penal clause of the bill, as agreed upon by the conference committee, now reads as follows:

And any person or persons, company or corporation, their agents or employees, who shall mine by hydraulic process—directly or indirectly injuring navigable waters of the United States—in violation of the provisions of this Act, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding \$5000, or by imprisonment not exceeding one year, or by both such fine and imprisonment, in the discretion of the court.

It is provided that this section shall take effect on the first day of May, 1893.

The words "relating to the working of hydraulic mines" are inserted in Section 24, so as to permit consultation with the Debris Commission, provided the legislature of California passes the bill now pending creating such commission. These are the most important changes resulting from the refusal of the House to concur in the Senate amendments.

The Washington dispatches are somewhat "mixed," as both Felton and Caminetti are reported in receipt of telegrams from the Executive Committee of the Miners' Association consenting to accept the amendment unchanged. This is incorrect, since no such dispatches have been sent to these gentlemen by the committee. In fact the association sent Judge Searles on specially to get the penal clause modified, as it has been. Mr. Caminetti appears to be making a little political capital by referring to the "kid-glove Sunday miners of San Francisco" and saying he did not approve the bill with original penal clause, while they demanded that he accept the bill.

He may have dreamed this, but has no better basis for the statement. The committee has not met of late, and when it did, sent no telegram to Caminetti or Felton. Individuals may have telegraphed their personal opinions, and this is probably what brought forth the statements in the dispatches. Mr. Caminetti, however, has no right to place the Executive Committee in a false light. The whole record will show that the committee fought for the amendments, and Mr. Caminetti himself was afraid they

were endangering the bill. Mr. Caminetti's statements may give him some brief "glory" as doing it all himself; but the apparent attempt to belittle the Miners' Association is silly, to say the least.

Combined Water-Wheel and Dynamo.

Our engraving shows a combination made by Mr. Dodd of the Union Iron Works, consisting of a Dodd Sigmoidal water motor and a Keith electric-light dynamo mounted on a base common to both. This engraving is made from a photograph of a machine used by Mr. Llewellyn at San Rafael, Cal., for lighting his residence by incandescent electric lamps. Besides being a very sightly piece of apparatus, it is more compact, and utilizes the power of the waterfall to a greater degree than if the dynamo were driven by a belt from the water motor.

This combination is made in all sizes by both the Union Iron Works and the Electrical Engineering Co., in San Francisco. It is especially advantageous in the lighting of mining works wherever water for tangential wheels is available. In the larger sizes, the combination on one base of an iron-encased wheel and electric generator, for power transmission, is the most simple arrangement imaginable for the purpose.

Mining Briefs.

ANTIMONY is selling in Liverpool at £42 to £42 10s per ton.

SOME excellent asbestos deposits have been found in the Grand Canyon district, Arizona.

THE demand for sulphate of copper has fallen off in England, and £15 10s to £15 15s is now the value.

THE United States sent abroad last year a great deal of copper. To England we sent 25,587 tons, and to France 2430 tons.

"FREE COINAGE OF SILVER," by John C. Henderson is the title of a paper highly spoken of by Senator Stewart, which will appear in the March *Overland Monthly*.

A SMELTER is being built at Pedrixna, north of Durango, Mexico. The promoters are C. P. Huntington, president of the Southern Pacific Co., and the Omaha and Grant Smelting Co., of Denver and Omaha.

THE Providence Mining Co., of Nevada county, is about to ship 100 tons of sulphurets to the Selby smelting works, but intend to put up their own chlorination works and attend to the sulphurets at home in the future.

LIVERPOOL and Swansea received last year from Chile 17,619 tons of copper, while from this country 25587 tons were received. Spain beat Chile last year, sending to the cities named 4910 tons of copper and 14,831 tons of precipitate.

SAN FRANCISCO exported by sea last month 3208 flasks of quicksilver worth \$133,260. Most of it went to New York. During January there were 2243 flasks of quicksilver received at this port, as against 1704 for the same month in 1892.

SALT LAKE CITY has raised a sum of \$100,000 in money and 160 acres of land as a bonus for the copper refinery to be erected by Posey & Green. Butte, Omaha and Chicago were competing for the plant, but this bonus is expected to bring the refinery to Salt Lake.

THE Nampa *Progress* says the excitement over the recent discoveries of precious stones in the Owyhee country, Idaho, has not abated. They may do something with their opal mines up there, but with the diamonds and rubies it is more than doubtful if any success is made.

AT the annual meeting of the Cape Copper Company, the chairman stated that 5670 tons of copper in ore had been raised during the year 1892, at a cost of 5s 2½d per unit, against 5100 tons in 1891 at a cost of 6s 4½d per unit, the profit being £61,000 in 1892, against £69,744 in 1891.

THE Salt Lake *Tribune* learns that 1,000 men are out of employment at Eureka, Utah, most of them on account of reduction in wages. A warning has been issued against nonunion laborers coming into camp. There is a great depression in the camp in consequence of the stoppage of work.

THE Deadwood *Pioneer*, speaking of the shut-down of the Harney Peak Co's tin mining operations, says that the mill was not in operation long enough to practically demonstrate the commercial problem of tin mining in the Black Hills. The *Pioneer* still believes that, with proper management, there are a number of tin mines in the Black Hills that will pay a reasonable interest on the investment.

FELIX KNIGHT who died at Pioche on the 4th, has for the past 20 years or more lived for the most part of the time alone in Silver Park district, working his silver mines and only making a shipment of ore when supplies were short. He wielded a large hammer with one hand and did quite as much execution as an ordinary man does with two. A few months ago he refused \$80,000 for his mines in Silver Park district.

THE State authorities at Sacramento are having the usual trouble adjusting the income of the State to the enormous demands on the public purse. Various State institutions, State officers and others who think they have a claim on public consideration, have already asked appropriations aggregating \$15,287,177 for the two years beginning July 1, 1893. The estimated income of the State, on a five-mill tax basis, will be about \$12,758,325 for these two years. It is plain that the squeezing process will have to be resorted to. No doubt many of the appropriations asked have no merit, while others can safely be reduced.

Coast Industrial Notes.

THE Los Angeles cable roads and electric roads are to consolidate in one company.

THE work on the new electric road on Twelfth street, west of Broadway, Oakland has been fairly started.

THE Southern Pacific has commenced track-laying at Santa Margarita toward the big tunnel. No water has been encountered in the tunnel work, and the big bore is progressing rapidly.

BETWEEN Niles and Decoto, Alameda county, is a bed of molders' sand, which is added to year after year by the wash from Alameda creek. This deposit is a very valuable one indeed, and yields a handsome revenue yearly to its owner.

THE new electric-light works, which will give light to Yuma and the new town of Yuma Heights, started up on the 13th and are running. The old town, so completely wrecked by the flood of two years ago, has arisen from the ruins, and has new water works and electric lights.

THE big reservoir at La Mesa, San Diego county, projected by the flume company will be begun at once, the contract having been let to Joseph Nickerson, who is to complete the work within 60 days. The dam will be 30 feet high, 278 feet long, and will impound 19,000,000 gallons of water.

THE new electric steamer built by Stacy Bros., was successfully launched at Yuma on the 13th inst. She will be used in the ore and mining trade between Yuma and the mines on the Colorado river. She is the largest boat ever built to be propelled by electricity. She will carry 50 tons on 20 inches of water.

A COMPANY is about to erect a plant in the vicinity of Los Gatos with which to concentrate the juices of fruits, berries and grapes. The evaporation is accomplished by the well-known film process, which consists of exposing a thin film of juice to rapidly-moving currents of warm air, precisely on the same principle as that used in evaporating cut fruit.

THE former machine-shop in the department of construction and repair at Mare Island navy yard is being fitted up for a toolroom. A second floor is being laid, and on this floor will be several partitions for use as offices and special purposes. One partition of the lower floor will be used for the molders in case sufficient funds are obtained to make other necessary improvements.

REPRESENTATIVES of a company of wealthy San Francisco business men, who are heavy owners in Nevada county gold mines, are in Nevada city making preliminary arrangements for constructing an electric railroad from that city to Marysville, 40 miles distant. The projectors promise that the line will be pushed through during the coming summer to Grass valley and will be completed the entire distance before 1895.

THE Board of Supervisors of Santa Clara county has granted three electric-railway franchises—one to Jacob Rich for a road from San Jose to Willows; another to J. H. Henry and J. P. Burke for a road to Meridian, and a third to F. M. Smith, Warren Olney and others for a road to Saratoga, 11 miles distant. Previous efforts for a road to Saratoga had failed, but the people rejoice that a road is to be built. It will carry both freight and passengers.

SOME of the new electric roads in Oakland are putting their curves very close to the corners of the streets. The Hayward Electric Company is now putting in a curve at the corner of Thirteenth and Washington streets. It is one of the sharpest curves in the city and comes within two feet of the sidewalk. Abrahamson Brothers, who own the building on the corner, have entered a vigorous protest against the work and have appealed to the Board of Public Works.

THE new wharf being built at Santa Monica by the Southern Pacific Co. has now attained a length of 4000 feet and will be built about 850 feet farther into the ocean. The portion now being constructed is about 130 feet wide and will accommodate seven lines of track. Coal bunkers 800 feet in length will be built in the portion of track not yet constructed. At the present sea end of the wharf the water at low tide has a depth of 38 feet. There will be a depth of 45 feet at the outer end when completed.

THE statement is made that the United States imports nearly a million gallons of olive oil, while California manufactures as yet but 11,000; that foreign pickled olives sell at \$4 a gallon in small bottles, while excellent California olives retail at \$1 a gallon from the barrel. This is reason enough for the cultivation of the olive and the manufacture of oil in Southern California, but the business requires the intelligence and persistence demanded for the prosecution of any skilled branch of industry.

DURING the past few months the Oakland, San Leandro and Haywards Electric Railway Company has been cutting into the passenger business of the Southern Pacific Company very largely. The electric cars run every 20 minutes from Oakland to Haywards, so that the large majority of people now never wait for a train, but use the electric cars instead. The Southern Pacific has determined to enter into competition for passengers. It will in a few days run trains to Haywards every hour during the day, and the fare will be placed lower than that of the electric road. It will be a case of steam against electricity.

A SMALL LAUNCH ENGINE is now being made at the Mare Island Navy Yard for the United States Coast Survey steamer Patterson. Her old launch engines are also undergoing repairs. According to instructions from higher authority, very economical methods are pursued by her officers. All the small lathe work is being done on board of the ship, a small launch engine having been fitted temporarily for that purpose. The more particular machine work is turned over to the machinists of the yard their own machinists doing all of the vise work. It has often been the case when outside vessels came to the yard for slight repairs, most of the small work would be done

by the ship's machinists in the shops, much to the annoyance of the ship mechanics and the destruction of the tools. This will, however, not be done in the future to any great extent, as orders have been issued to the contrary unless under extenuating circumstances. In the manufacture of the launch engine for the Patterson, the shops are placed in direct competition with the Herreshoff people, and the engine is to be very similar to that made by them, except that it is not as simple in detail and involves much more labor. Considerable interest is felt in the outcome by the officers and mechanics.

THE Alaska Packers' Association, which was formed last week to control the salmon industry, has completed the organization of the company and elected all the officers. The offices of the company will be located at the corner of Front and Market streets and are now being fitted up. All the canneries in the scheme have received their pro rata of stock in the new association, and the plan of operation for the coming season will soon be decided upon. The object of the company is to curtail expenses and limit the output, and all Alaska canneries except two are in the pool.

THE Board of Directors of the Sacramento Box and Supply Company has organized by electing the following officers: W. F. Barnes, president; D. O. Mills & Co., treasurer; W. F. Cronmiller, secretary and general manager. The company succeeds the firm of W. F. Barnes & Co., and organized for the purpose of manufacturing and selling lumber, doors, sash blinds, grape and berry baskets, etc., has just completed a large two-story building at Twelfth and B streets, Sacramento, where it will give employment to a number of girls and boys in the basket-making department when the season opens.

A MEETING of business men of Fresno was held on Tuesday to consider the steps to be taken to raise the required bonus for the proposed Monterey and Fresno Railroad. Some thought the best plan would be for twenty-five men to subscribe \$20,000 apiece. Others were of the opinion that the public in general should be asked to subscribe. Committees were appointed to see to the right of way to this city—one to invite cooperation of the county Supervisors and the City Trustees in the matter of the right of way and another to stir up the colonists. Theodore Kearney proposed that the subscriptions be made part of the bonded indebtedness of the road with the understanding that they would have to be paid along with the other bonds should the road ever be sold or get into the hands of the Southern Pacific.

A CODFISH COMBINE has been perfected in this city under the name of the Union Fish Company, and last season's catch of codfish taken in the Behring and Okhotsk seas and cured at Lynde & Hough's station at California City and the McCollam Fishing and Trading Company's Station on Kashaw's island, opposite Saucalito, has been disposed of to the Union Fish Company. The two companies which form the combine retain their individuality to a limited extent, but will operate their vessels for mutual benefit. The reason given for the combine is that competition has put down the price of codfish to such a figure that the industry could not be profitably conducted so as to hold out against cheap and adulterated articles which are put on the market from the East. The codfish industry has been running down on this coast since 1883, when there were 17 vessels in the service. Last year there were only five or six schooners and barkentines. While the fish caught the last few years were of good size and excellent quality—showing that the banks in the Behring and Okhotsk seas were improving—competition in this city has nearly killed the industry.

SUPERINTENDENT BROWN, of the Carlson-Currier silk mills at Petaluma, does not believe that California women can reel silk from cocoons profitably. He says: "When the ladies of this city first organized the Petaluma Women's Silk Association, I told them we would purchase all the reeled silk they brought to us which would compare favorably with that which we import from China and Japan. In those countries a silkreeper is paid but six cents a day for labor, and silk cocoons are very cheap, while in California a silkreeper cannot be hired for less than \$1 per day, and the cocoons cost \$1.40 per pound. The reeled silk is not bulky, so shipping costs but little, and the duty on raw silk is very light. I cannot see how the reeling of silk can be made profitable in Petaluma. The ladies will be out of pocket a great deal in hiring somebody to teach them how to reel, and about the only thing that would keep them together would be Government appropriations. They have worked hard in their undertaking and have had all the advantages that could be expected. The railroads and newspapers have extended them many courtesies, and they are to be admired for their perseverance, but for my part, I do not believe in their staying with it any longer."

C. J. WETMORE of the viticultural commission has made the following estimate of the wine production of California during 1892:

	Gallons.
Napa county.....	2,500,000
Sonoma.....	2,750,000
Alameda.....	1,250,000
Contra Costa.....	300,000
Santa Clara.....	2,750,000
Santa Cruz.....	250,000
San Joaquin.....	300,000
Fresno.....	750,000
Los Angeles and South.....	500,000
Sacramento and North.....	500,000
Other counties.....	500,000

Total for State.....12,350,000

ABOUT a month ago the men who had been employed at Moody's wool warehouse, on Bluxome street, quit work because the owners wished to pay them \$2.50 per day, rather than 25 cents per 100 pounds. Girls were at once employed in their places. The employment of women for this work was an experiment that had never been tried in the California sorting rooms, and the mill owners watched the result very carefully, intending to make the same change should it prove a success. The change has been decided to be satisfactory and will help the demand for California scoured wools, as the wool is being more uni-

formly sorted. Catton, Bell & Co., when the season opens, will also employ girls exclusively. For a number of years S. P. McClellan has employed Chinese as sorters, but they will have to go, and the girls will succeed them. "I am thoroughly in sympathy with the change," said Mr. McClellan. "I have not employed Chinamen for any love of them, but simply as a business proposition. I buy my labor just as I would buy anything else, in the cheapest market, and I could get more work for my money by employing them. Now that the girls have demonstrated that they are able to do the work I shall put them into my place as soon as possible, and I am willing to pay them more than I have paid the Chinese if they do as much work and do it equally well." At other wool-sorting houses on Bluxome and Townsend streets the same change will be made. There will be employment for at least 250 girls when work is in progress in all the mills. Many applications for employment have already been received.

DREDGING in the San Antonio estuary, which forms part of the Oakland harbor, will be commenced next week by the Von Schmidt Dredging Company, under a subcontract with John H. Hackett, who, representing the Pacific Coast Dredging and Reclamation Company, has contracted with the United States Government to do the work. The terms of Hackett's contract with Von Schmidt are private, but those of Hackett with the Government are that he shall dredge the channel of the Oakland Harbor from Webster street westerly, in front of the city, to a depth of 20 feet at low water, along such lines as the Government engineer in charge shall direct. From this channel 250,000 cubic yards of spoil must be taken, and 40 cents a yard will be paid for the work. Another contract with Hackett is that he shall dredge the channel lying in front of Brooklyn to a depth of eight feet at low water, taking out 200,000 cubic yards at the rate of eight cents a yard. The difference in the rate for dredging is on account of the difference in the depth and quality of the spoil to be cut and pumped over the marshes by the hydraulic dredger. The Government will pay over \$124,000 for the work, and Alameda county property-owners are happy over the contemplated improvements to the harbor.

Personal.

COL. WM. T. SUTHERLAND, president of the Holmes Mining Co. of Nevada, has returned from a visit to England.

J. T. PARKS now has a fine superintendent's residence at the Kennedy mine, Amador county, and has moved into it with his family.

EVAN WILLIAMS, the well known mining and mill man of Nevada, is about to remove to this city to engage in the abattoir business.

PROFESSOR R. H. TUCKER, now at the observatory in the Argentine Republic, has been appointed astronomer at the Lick Observatory at \$1800 a year.

JUDGE NILES SEARLES of Nevada county, ex-Chief Justice of the Supreme Court, has been appointed a Commissioner of the Supreme Court vice Foote, resigned.

MARTIN JONES, capitalist and mining operator of San Francisco, who is president of the Belmont Company and a shareholder in the Albany mine, has been visiting his mines in Amador county.

JOHN B. HOBSON, the well known Placer county hydraulic miner, who for a year past has been operating a large hydraulic property in British Columbia, is spending the winter in California, and is for the present living in San Leandro, Alameda county.

W. T. ROBINSON is an old California miner who has of late been prospecting on the Kenai peninsula, Alaska, where extensive veins of coal have been found. Many of the coal veins crop out along a sandstone bluff overlooking Kachekmak bay, and can be seen a mile away, one above the other. Some of these veins contain thousands of tons of clear coal, which can be easily loaded on vessels. Reefs of the article have been washed out by the action of the water, and great quantities can be found on the beach all around the peninsula. Kachekmak bay is a landlocked harbor, making it perfectly safe for vessels at anchor. The distance from San Francisco is but nine days by steam and from 14 to 25 for sailing vessels. The cost of mining and freighting the coal to San Francisco would be less than \$3 a ton. Across the bay from the coal veins are found ledges of gold, silver and lead. Sixty miles across the peninsula at Tornagua arm, the head of Cook's inlet, a gold placer thirty miles in extent was discovered last summer, which was worked by four or five prospectors who took out from \$3 to \$5 a day with rockers. Later in the year another placer was found near Cook's inlet, opposite Kenai peninsula, from which it is reported that as high as \$150 a day to each man was taken out by means of the sluice box. This is scale gold and resembles that found in Calaveras county of this State.

JACK RIVERS, a miner in the employ of the Pyramid Co., N. M., was killed in the Henrietta mine last week. He put in some shots and climbed out of the mine, but went back before the last one went off. His body was literally filled with pieces of rock. A miner in Frank McCabe's mine, at Big Bug district, Arizona, had better luck. It seems that two men were in the bottom of the shaft and had just ignited the fuse which was to explode twelve sticks of giant powder. One man went up in the bucket and the other started to climb a rope to the ladder. When a short distance up, the latter man fell back. His light went out, as did also his partner's, and he yelled that he was lost. His partner called to him to pull the fuse, but his voice was drowned by the explosion of the twelve sticks of powder, which he felt sure sounded the death-knell of the man in the bottom of the shaft; but, strange to say, the man escaped unhurt. If he can tell how it happened he ought to for the benefit of the mining community.

Mines at Elk City, Idaho.

ELK CITY, IDAHO, Feb. 4, 1893.

TO THE EDITOR: Elk City is situated in Idaho county, Idaho, at the head of the south fork of the Clearwater river about 100 miles from Lewiston, the head of navigation on Snake river. It was discovered in 1862 and was very rich in spots, but the spots are nearly all worked out now—that is, the rich spots. Yet there are several creek bottoms that prospect fairly well. Being too deep for the old-timers, these immense bodies of gravel (in some places from five to ten miles long and from 300 feet to half a mile wide) have lain dormant for over thirty years. On one of these creeks a Chicago company has located about 500 acres of ground, and last season put in a dredge at a cost of \$42,000, the creek being too flat to work by flume. On another creek a California company, under the management of Mr. Dan Greer of San Francisco, have acquired by location and purchase about 200 acres of ground on which they are putting in a bedrock flume and two giants. On still another, or rather three more creeks, Mr. Greer has located and bonded about 1500 acres of ground on which he intends to put a bedrock flume and run a bedrock tunnel nearly a mile long. Still there is a score of other creek-bottoms in this immediate vicinity just as rich as these awaiting the advent of capital to open them up and make good paying mines of them. California capital is taking quite a hold here lately, especially in placer ground, for there is no debris law to stop the miner, and anyhow miners make the laws here.

The quartz of this camp has been as much or more neglected than the placer. I have prospected through four of the chief mining States and I have never seen such wonderful ledges of refractory gold rock as I have seen here. There are hundreds of ledges of very fine-looking sulphuret rock of from four to twenty-five feet wide, and assaying from \$12 to \$65 to the ton, and several of them can be traced for miles on the surface.

This is the most inviting field for capital for either placer or quartz that I know of. The country is out of the way of all travel, and mining men never even hear of it. It is so far from a railroad or mining center that it has been entirely overlooked, and most of those interested are old men that have lived here since the sixties and made a living by coyoting around the bars on shallow places and took no interest in quartz or big hydraulic placer mining. They made an easy living without dredges or giants. The ore of the district is generally iron sulphurets where gold predominates in value. When the ore is rich in silver, which is only in a few places, arsenical pyrites take the place of the iron sulphurets.

The country rock of the district is gneiss with dikes of syenite and porphyry, running northeast and southwest, between which some very fine contact veins are found, although the best ore is generally found in the fissure veins. The Blue Dragon is a true fissure vein four feet wide, the ore of which assays \$20 to \$65 per ton and is very uniform. The Gentle Annie, an extension of the Blue Dragon, is similar in character to the latter. Ore from this ledge sent to Denver for treatment by the cyanide process gave returns \$34 per ton and a saving of 94 per cent.

The Buster is a fissure vein and, like the other, there are five or six extensions located on it.

The Mineral Hill is also a fissure vein, and it is also exposed by tunnels and shafts a distance of 7,000 feet. These three veins are all grouped inside of two square miles.

The Lillie May is a contact vein and is six and a half feet between walls. The ore assays from \$10 to \$42 per ton. The Blanco is also a contact vein—or rather a mountain. It is from 12 to 35 feet between walls and assays from \$10 to \$28 per ton. This is the largest body of ore in the camp. There are a lot more, but I have made this sketch too long now.

M. L. MURRAY.

THE break in the Santa Cruz division of the Southern Pacific is giving Superintendent Fillmore more trouble than any other portion of the system. It seems impossible to find any means of fixing the tunnel so that the next rain will not almost knock out all previous repairs. The mountain is continually sliding, slowly but surely, and the work of months is undone in an hour. Mr. Fillmore says that the repairs would probably have to be postponed now until after the rains were over for the season. "We are about discouraged in this work," said he, "for no matter how strong our braces, or how much work we have done on that tunnel, some morning we go there and there is nothing to be seen on the track but a mass of rock and sand. No human power can withstand the awful force and might of that sliding mountain."

SENATOR BERRY has prepared a proposed amendment to the constitution, designed to relieve the legislatures of a very burdensome question which now takes up much of their time each session. The resolution reads: "The legislature, by general and uniform laws, may provide for the formation of new counties; but that no new county shall be established which shall reduce any county to a population of less than eight thousand; nor shall a new county be formed containing a less population than five thousand; nor shall any line thereof pass within five miles of the county seat of any county proposed to be divided. Every county which shall be enlarged or created from territory taken from any other county or counties, shall be liable for a just proportion of the existing debts and liabilities of the county or counties from which such territory shall be taken."

VANDEBILT is the name of a new district on the Mojave desert, in this State. The town at present consists of 200 people, 40 tents and one small frame house. Lumber costs \$90 per 1000 feet, water 3½ cents per gallon and potatoes 5 cents a pound. The railroad from Goff's station toward Vanderbilt is graded for 14 miles and there are five miles of track laid.

Where the Columbia River Gold Comes From.

The placer gold found in the northern part of the State of Washington, on the banks of the Columbia river, is very fine scale gold. The pay dirt is only six inches in thickness, except in places where it has lately been washed down from the original deposit. At same level on each side of the stream, about six feet above high water mark is seen the strata of red and brown earth and gravel that carries the dust. The gravel is about the size of a pin head to boulders that are from four to eight inches in size each way, generally flattened both sides and twice the width in length. This coarse gravel is made of several kinds of rocks, granite predominating, considerable quartz, some greenstone and slate, but few of the brimstone, dolomite. So the character of the gravel helps determine whence the gold came from. There is no gold found higher up on the benches, so we must conclude that the deposit was made at one period of time and at a comparatively late date. There are no large nuggets found, only one kind of gold and nearly of one size; the shape of this dust gives it a peculiar motion under water. None is found on bare rocks in low water, but very little in deep channels that have become dry; the most favorable place is in shallow water with but little current and at high water mark, and it is spread evenly with the gravel on benches of 300 feet or less in width—all of these things must be taken into account in order to determine where it came from and how far it traveled before resting.

In early days an ounce per man per day with sluices was the best pay reported from reliable sources, generally one-fourth that much was taken out; finally the Chinamen worked large fields of it, not making over \$1.50 per day, and even less. No doubt there are places on the Colville reservation side of the river and in that portion soon to be thrown open to the explorer, many good bars that will remunerate with sluice and rocker.

The summer of '92 I concluded to try and find the source of this deposit, thinking it might lead me to the mother lode. Going up the Pend d'Oreille river I found the same deposit of rock and gravel, the same gold with another kind that was much coarser and darker in color and more valuable. The same deposit was found on the Columbia river above the mouth of the Pend d'Oreille. So I concluded the source was not a mother lode, but a large and extensive belt of gold-bearing rock at or near the head of the several streams putting into the Columbia from the east. Going up Little Salmon river the same deposit was found at the forks of the stream, showing plainly that both forks had their supply of gold from the same field, therefore it was to the north and east. Sullivan creek, that empties into the Pend d'Oreille several miles above the Salmon has the reputation of having the same kind of gold in a lesser degree, and that stream comes from the northeast. So by the map one can locate this gold field, that I found to be from three to fifteen miles wide and of unknown length, at least thirteen miles long. Following up the south fork of the Salmon river, (I will say here that the coarse gold on the Salmon river is supplied by ledges within six miles of the mouth of that stream, as none of that kind of gold is found above that point, probably in or near the mineral belt discovered by Death-on-the-Trail Proctor last season,) most of the country rock for the first 15 miles is dolomite, not much show for a gold ledge in such rock; then comes a dyke of mica slate with large veins of quartz miles in length. Here was supposed to be the mother lode, but each one proved to be barren, yet up the stream into dolomite again I found colors to every pan of the same character as that found on the Columbia. As we approach the head of the south fork the gulches are deeper, the timber larger, the mountains higher, the Sullivan interlocks with the Salmon and Priest rivers, a sharp divide between each that runs up in ragged peaks where snow remains the year round. Here all the panning fails to raise a color. Had I passed the mother lode? To be sure there is a dyke of chloritic slate 1000 feet wide crossing from north to south full of pockets of cellular quartz, but two weeks of hard work proves that there is nothing in it. So up the highest peak 8000 feet high to see what kind of rock is there—on the east side of that mountain, called Snow mountain by prospectors, lay tilted over on its side a rock nearly a mile in thickness that was once a placer field now turned into stone. There were all kinds nearly of round water-worn pebbles and boulders imbedded in this slate rock, from the size of a pea to four foot granite and quartz, shaped like hen's eggs and sticking out where the broken places occurred. Some strata of brown color were taken and pounded up and panned out and the proof showed up with a half dozen colors of Columbia river gold.

The higher peaks of that divide, cut by tributaries of Priest river, Sullivan creek and Salmon and Kootenai rivers, hold the remnants of a once mighty placer field. Those mountain tops were once a valley, and before that a mighty flood passed through it carrying from the far north the gravel, sand, gold, clay and sediment that ages after made what is called conglomerate rock. The forming of channels, draining this large scope of country by the streams mentioned above, lowered the ledges of this plateau; what was left is now our mountains, the rock tilted over towards valleys or entirely washed away, down to the bed rock beneath the later deposit. The absence of colors on the western slope in the near vicinity of the summit, goes with the fact that there the conglomerate is all gone down the valley. Many hundreds of feet of the underlying limestone is cut out, so no colors could remain under such circumstances.

I could give pages of argument in favor of this theory, but prefer to wait of space to give you these few cold facts. It may save some other prospector months of labor and disappointment. It well repaid me for the summer's work.—H. S. BACK in Northwest Mining Review.

The Use of Asphaltum for Reservoir Linings.

Read by MR. JAS. D. SCHUYLER, C. E., of San Diego, at the December meeting of the American Society of Civil Engineers.

For a number of years past experiments have been made in rather a small way in various parts of California in the use of asphaltum for reservoir linings, particularly in the southern portion of the State, where the natural product abounds in a great variety of forms, from hard rock to liquid "mineral tar," so called, oozing from the ground in springs. The natural properties of asphalt seem to render it a useful material from which to form a water-tight coating for reservoirs. It is insoluble in water, and neither acids nor alkalis dissolve it or affect its cohesion; hence it imparts no taste or color to water coming in contact with it. It is elastic and will yield to a considerable settlement of the surface on which it lies without cracking or losing its integrity. It is easily repaired, and new material may be made in unite perfectly with the old, wherever a path may be needed.

The writer has had occasion to examine a number of small reservoirs so lined, and in almost every case found them in satisfactory condition and generally impervious to water. One of these that had been in use for four years at the town of San Buena Ventura, was an extreme example of the serviceability of asphalt. A circular reservoir of about 100 feet in diameter and ten feet deep had been excavated in light, sandy and gravelly soil for perhaps one-third of its depth, the material excavated being used in the embankments. It was paved on the bottom and sides (sloping 1 to 1) with cobblestones laid in mud, the spaces between being partially filled with the mud mortar. When dry, this rude masonry was covered with a thin coat of liquid asphalt, poured on hot and spread with brooms. The thickness of the sheet did not exceed one-eighth, and in places was not over one-sixteenth of an inch thick. The reservoir was not covered. After being filled with water, one portion of the banks was said to have settled outward more than two feet without breaking the integrity of the lining. The cost of the lining was very small; it has required few repairs, and bids fair to render service indefinitely. Another reservoir examined by the writer was excavated in firm shale and soft sandstone, with nearly vertical sides, on which the hot asphalt was successfully applied. This was a small house-service supply reservoir, and had been a year in use without repairs when examined.

Other instances of the use of asphalt to repair cracked and broken concrete linings of reservoirs were noted, in all cases with success. The writer subsequently constructed on his own premises a circular reservoir 64 feet in diameter, 7 feet deep, which he lined with asphalt $\frac{1}{2}$ inch thick. The side slopes were 1 to 1, and the first coat consisting of a mixture of 15 per cent of La Patera asphalt (which contained by analysis, 66 per cent of pure bitumen) and 85 per cent of beach sand, after being heated to a temperature of 300° was spread with hot rakes and consolidated by means of hot tampers and smoothing irons. It was laid in sections 2 feet wide, half the height of the slopes. The edges should have been painted with pure liquid asphalt before the adjoining section was laid next to it, and it was, doubtless, owing to a neglect of this precaution that, after being in use one year, small cracks appeared, outlining the joints where the various sections were laid. These cracks were all repaired, however, with half a barrel of asphalt and the labor of one man for three days, and the reservoir is in perfect condition after two years, although exposed to the sun. The sheet of asphalt was tacked to the slope by means of strips of strap iron 6 inches x $\frac{1}{4}$ inch x $\frac{1}{2}$ inch, driven in at intervals of 18 inches in each direction. A second coat, consisting of La Patera asphalt fluxed with about 10 per cent of "mineral tar," the heaviest of the natural oils of California, heated to a temperature of about 250° F., was applied over the entire surface. It was poured on as thinly as possible and ironed down with hot smoothing irons. Its thickness averaged about $\frac{1}{4}$ of an inch.

With this experience, and after a careful examination of the principal asphalt beds of southern California, as well as the sea walls laid in asphalt and described by W. C. Ambrose, M. Am. Soc. C. E., in Vol. XXIV. of the *Transactions of the Society*, the writer felt justified in recommending the use of California asphalt for the lining of two large distributing reservoirs constructed at the city of Denver, Col., by the Citizens' Water Company. These reservoirs, known as the East and West Ashland Avenue Reservoirs, lie side by side, and were excavated to their full depth of 32 feet on the upper or higher side, the material being used to form artificial embankments on the lower side, where the minimum depth of excavation below the natural surface was 6 feet. They are intended to be filled to a depth of 26 feet, and there was, therefore, on one side 20 feet in depth of water to be supported against a made bank. The whole of the West and a portion of the East Reservoir were excavated during the winter of 1890-91, when there was a good deal of frost in the ground, and although a 12-ton steam-roller was employed to consolidate the banks, a considerable settlement was anticipated, which would have been fatal to a concrete lining.

The dimensions of the West Reservoir were as follows: bottom, 341 x 256 feet; top, 350 x 420 feet; maximum depth, 32 feet; depth to roof line, 29 feet; depth to high-water line, 26 feet; side slopes, 1.33 to 1; capacity, 22,000,000 gallons. East Reservoir: bottom, 152 x 494 feet; top, 235 x 580 feet; depth, slopes and capacity the same as the West Reservoir.

The material excavated consisted of 2 or 3 feet of sandy loam, 12 to 15 feet of hard clay impregnated with alkali, and 8 to 12 feet of shale, the "bed rock," so called of the country. On the completion of the embankment the slopes were sprinkled and rolled with a slope-roller weighing 5 tons, drawn up the slopes and lowered by an engine placed on a track along the top of the banks.

At the time the West Reservoir was completed and ready for lining, it was found impossible to get the amount of California asphalt needed within the time available, and it was decided to use Trinidad asphalt, which could be ob-

tained on the ground from the Barber Asphalt Company, then engaged in paving the streets, and having in operation a capacious plant for melting and mixing the materials. A contract was made for the delivery of the materials at the reservoir at a given rate per day. It had to be hauled in wagons about 2 $\frac{1}{2}$ miles, and as the roads were muddy and the weather cold, some of the asphalt chilled on the way and had to be rejected. All that was put on was supposed to be of a temperature of 250° and over. Beginning at the bottom, the slopes were laid in horizontal strips about 10 feet wide, the thickness averaging about 1 $\frac{1}{4}$ inches. It was spread with hot rakes, tamped as hard as possible with square tampers, kept hot and frequently changed, and ironed with heavy, hot smoothing irons. While the sheet was still warm, anchor spikes, cut from strap iron 1 x $\frac{1}{2}$ inch, 7 to 8 inches long, were driven through the asphalt into the bank, in rows one foot apart, about 12 inches from centers in the rows. Every other row was driven down flush with the surface, the alternate rows being allowed to project 1 $\frac{1}{2}$ inches above the surface temporarily to serve as a rest for strips of 2 x 4 inch lumber, placed loosely above them on the slope, thus forming steps for the workmen to ascend while working on the space above. When the finishing coat came to be applied, these projecting spikes were driven flush and all painted over. The bottom thickness was about one inch. After spreading and tamping, it was rolled with a cold steam roller weighing five tons. The finishing coat of refined Trinidad asphalt, fluxed with residuum oil, was poured on hot, from buckets shaped like a coal hod, and ironed over with hot smoothing irons, heated to a cherry red. These irons had to be passed over the surface quickly, and when first applied produced a yellow smoke; but it was found that perfect cohesion with the first coat could not be secured except by thorough ironing with very hot smoothers. When finished, the surface had a bright, glossy appearance as though varnished. The cost of this work was as follows:

FIRST COAT.

1304 tons, 20 per cent asphalt mastic, 80 per cent sand at \$12.....	\$15,648 00
15 tons, 15 per cent asphalt mastic, 85 per cent sand at \$10.....	580 00
86.21 tons liquid asphalt, fluxed with oil, at \$40.....	3,448 40
Fuel for heating irons and for steam roller.....	276 02
Lights.....	36 00
Tools.....	179 75
Peg irons—material, cutting and dipping in asphalt.....	650 00
Labor.....	1,921 50
Use of roller six days.....	60 00
Total.....	\$22,799 67
Area of surface covered, 154,580 square feet. Cost per square foot, 14 94-100 cents.	

The East Ashland Avenue Reservoir was lined with California asphalt in July and August of the current year. The material was furnished from the Santa Barbara county beds of the California Petroleum and Asphalt Company, the asphalt being from the La Patera mine and the flux from Las Conchas mine, near Carpinteria; was prepared on the ground by the Blake Asphalt Company of Denver.

The La Patera asphalt mine is one of the most interesting deposits of rock asphalt on the Pacific coast. It was discovered four years ago by an outcrop a few feet from the shore of a small estero, within 100 yards of the surface of the ocean. The principal part of the deposit seems to be below the level of the ocean, the lowest workings being now 70 feet below tide level. The asphalt is mined out in masses of from 1 to 20 cubic feet, by means of long wedges. A peculiarity of the mining is the fact that all picks and wedges become sharper with use and soon take on a keen edge. The asphalt is brittle, is easily mined, and is not sticky, nor does it run together in a solid mass on being piled in the sun. It is remarkably uniform in quality, and carries 55 to 68 per cent of bitumen, of which but 9.24 per cent is volatile at 1100° F. It is sold at the mine for \$20 per ton. The fluxing material known as Las Conchas asphalt is obtained from an extensive deposit along the seashore near Carpinteria, some 30 miles east of the La Patera mine. It is richer in oils and will volatilize 4 per cent at 300°, and 86.25 per cent at 1100° F. It carries 12.58 per cent of nonvolatile or "fixed" bitumen, besides the 86.25 per cent of volatile at 1100°, or a total of 98.83 per cent of bituminous matter and 1.17 per cent of mineral. The process of extracting it from the sand in which it is found is by passing it through a long cylinder of peculiar construction, called a "cochleon," which is made to revolve in vat of boiling water. The sand passes out of the end of the cylinder clean and white, while the asphalt floats to the surface of the water, and is then specially treated with hot compressed air to drive off the moisture. It is shipped in barrels, and is a viscous mass of somewhat less fluidity than "cold molasses" in ordinary summer temperature.

In preparing the mastic for coating the reservoir, the proportion of the La Patera asphalt and Las Conchas flux used was about 78 per cent of the former to 22 per cent of the latter. It was boiled in open kettles for about 12 hours, at a temperature of 250° to 300°, and frequently stirred to prevent burning or sticking to the bottom. The sediment that settled to the bottom of the kettle was removed with long-handled shovels, and used later on in another portion of the work for an asphalt concrete. For the first coat, 20 per cent by weight of this mastic was mixed with 80 per cent of sand (previously heated to the same temperature), in a cylinder provided with strong paddles. The mixing occupied about two minutes, when the charge was dumped into a cart standing underneath the mixer, whence it was conveyed to the bottom of the reservoir and there dumped upon wooden platforms, and thence taken in hot scoops to the spot where it was applied. The spreading and raking were similar to that described in the other reservoir, but the compression of the asphalt was accomplished by means of bot rollers, instead of cold rollers, tamping-irons and smoothers, a method which accomplished the work in a superior manner to the former process. These rollers are formed from sections of cast-iron pipe, turned off smooth upon the outer surface, and

fitted with a hanging fire-basket inside the cylinder, in which a fire was maintained. For the bottom work a 30-inch pipe was used, and for the slopes the pipe was but ten inches on account of the weight. This was pulled up the slopes by means of a $\frac{3}{4}$ -inch wire cable, passing over a pulley at the upper end. Six to seven men were required to manipulate this roller, besides a man to guide the roller with a long handle. The result of hot rolling was to consolidate the sheet of asphalt into a compact mass, driving out the air and producing more perfect cohesion of the particles than is possible by tamping, ironing or cold-rolling, for the reason that the asphalt is worked while it is still hot, and the roller passes over it so quickly and presses it so thoroughly that it has no opportunity to chill or cool off before it is compressed, and the hot roller keeps up its temperature until the work of consolidation is complete. Hot rolling is as essential to perfect work in asphalt as thorough tamping is to successful results in cement concrete.

The weight of the mixture of asphalt and sand, after being compressed, was found to be 127 pounds per cubic foot. The total surface area covered below the roof-line was 143,667 square feet, requiring 2,302,837 pounds of the mixture, or about 16 pounds per square foot. This gave an average thickness of the sheet of 1.53 inches. The sheet of asphalt was pinned to the slopes in a similar manner to that employed in the other reservoir, the pins being driven one foot apart in alternating rows, except when the shale was too hard to admit of the strap-irons being driven into it. This occurred over about one-fifth of the area, and there heavy sixpenny steel wire spikes were driven somewhat closer together.

The second or paint coat of pure asphalt was applied after the first coat was completely finished, and was thoroughly ironed with redhot smoothers, to secure as perfect adhesion with the first coat as possible. This result was attained perfectly, except in spots where dirt had become ground into the surface of the first coat by the tramping of muddy boots after rain. The most satisfactory way to insure a perfect contact and cohesion of the two coats is undoubtedly to apply the second coat immediately after the first is laid and while the latter is still warm and clean, but there were many little reasons and objections raised by the "expert foreman" to this method of doing the work, which might have been overcome and should be overcome in the execution of any similar work to insure the most perfect results. The thickness of the second coat was from one-eighth to one-quarter inch. It has a leathery consistency, toughness and elasticity, and although it manifests a tendency in warm weather to creep and gather in wrinkles down the slopes in both reservoirs, it never breaks, and remains impervious to water. The total amount of asphalt used on the second coat of the east reservoir was 178,470 pounds, or 1.24 pounds per square foot.

The cost of materials was as follows:

First coat.....	8.98 cents per square foot
Second coat.....	2.48 " " "
Total.....	11.46 " " "
Labor, fuel, spikes, etc., cost for both coats.....	1.99 " " "
Total cost for labor and materials.....	13.45 " " "

When the interior lining of the east reservoir was finished, the slopes above the roof line of both reservoirs were covered with a heavy coating of asphalt, $\frac{2}{4}$ to 3 inches thick. This was carried entirely over the top of the embankment between the two reservoirs, and for a width of five feet over the top of the banks surrounding them, forming a substantial pavement or pathway entirely around each, at a cost of \$4218.59 for materials and about \$700 for labor.

The total expenditure on both reservoirs on account of asphalt work was \$48,498.69, or about \$100 per 1,000,000 gallons of storage capacity. A reasonable estimate of the cost of lining these reservoirs in an equally substantial manner with cement, concrete, brick or stone exceeds this figure 100 per cent, although this was not the chief motive for adopting asphalt in preference to other materials.

At the time the west reservoir was lined the embankments were fresh and had been hastily constructed; the reservoir was imperatively needed for immediate service, and a material for lining was required that would stand the vicissitudes of the emergency without serious impairment. The result proved the wisdom of the choice, as settlement did occur, although not as great as anticipated. A fissure was opened in the lining, about ten feet below the roof line, on the highest part of the made bank, the crack being some six inches wide and 100 feet in length, but it was repaired without drawing the water off, at an expense of \$20. During the past winter a severe test was applied to the lining to prove its tenacity and hold upon the bank. Ice formed to the thickness of 18 inches when the water stood within eight feet of the top, and, while it was frozen fast to the lining all around, the water was lowered and raised again three to four feet, without the slightest injury to the asphalt. There was not the same urgent reason for lining the east reservoir with a flexible material, as the embankments had a year's settlement and were reasonably solid; but with a year's experience in the west reservoir, and a feeling of confidence in being able to improve upon the method of lining, as well as upon the materials and mixtures, there seemed no good reason to change for a more costly lining.

A few of the special difficulties encountered in the work may be of interest in the way of suggestion. A small quantity of seepage water, following the seams in the shale near the bottom of each reservoir, had to be taken care of, and caused no little annoyance. It was insignificant in quantity—not exceeding one gallon per minute in all—and was disposed of by cutting deep drains in the bottom and up the slopes as high as the moisture appeared, filling them about one foot deep with broken stone, covering them with plank, and then ramming in earth to the top. These drains converged to collecting wells, into which short sections of 12-inch cast iron pipe, with the hell ends turned upward, were inserted; and these were kept baled out during the progress of the work. The asphalt was brought up

to these pipes and well cemented to them. When the lining was completed, these pipes were capped with light cast iron plates, fitting into the hells, in the center of which was placed a two-inch flap valve made of sole leather, with an iron disc on top to hold it in place against a pressure of a few ounces. These are sufficient to admit the water freely into the reservoir when it is empty, without exerting any appreciable lift upon the asphalt sheet, while they will close to prevent leakage when the pressure in the reservoir exceeds that of the subsoil waters. There are about 15 of these valves in the two reservoirs. They seem to serve in a satisfactory manner the purpose for which they were designed.

The crumbling of the surface of the slopes, when dry, especially after a little rain, caused no little inconvenience, as the dirt rolling down would become mixed with the hot asphalt, as it was being applied to the slopes. To remedy this a portion of the slopes of the east reservoir was plastered with a thin coat of cement, lime and sand mortar, about one-half inch thick. This, when dry, made a smooth, clean surface on which to lay the asphalt. The writer is inclined to the opinion that wherever asphalt is used on earth slopes of reservoirs, this preliminary plaster coat should in all cases be applied; and it should be laid with care, nearly one inch thick, the cost of which should not exceed five cents per square yard. On this should then be spread a thin coat of liquid asphalt, similar to the finishing coat, as the foundation for the paving mixture with sand, which latter may advantageously be reduced in quality to about 16 per cent of mastic to 84 per cent of sand. This method of lining would render the paving coat impervious to subsoil water as well as to the water of the reservoir, and thus preserve it from the slight tendency to softening under the action of water, wherever compression is not perfectly accomplished and the sheet is at all porous. The finishing coat of liquid asphalt really constitutes the lining. The paving, or body coat of asphalt and sand, which is a body for the finishing coat to cling to, is only impervious to water where compression is absolutely perfect.

With the utmost care there will always occur spots where compression is imperfect, due to a variety of causes, most potent of which is inequality of cooking, the occasional burning of a batch, the application of it at too low a temperature, the slight yielding of the foundation, the use of tools insufficiently hot, etc., etc. For this reason the writer recommends that the body coat be laid between two coats of the liquid or pure asphalt. By "pure" is meant a mastic containing at least 75 to 80 per cent of bitumen. Under these conditions, and with the exercise of watchful care over every stage of the work, the writer believes that a reservoir lining may be made with asphalt that will be of indefinite serviceability.

The Russell Process.

From a little pamphlet issued by the Russell Process Co., of Park City, Utah, we take the following summary concerning the improved method of lixiviation for free and rebellious silver and silver-gold ores and tailings, either raw or after roasting:

The Russell process, both metallurgically and economically, occupies the place formerly held by: first, the Kiss, Patera, or old leaching process; second, amalgamation of silver and silver-gold ores; third, smelting of "dry" ores and ores averaging not over 15 per cent lead, or such as do not contain sufficient lime or iron to make them desirable as fluxes in smelting.

The Russell process has been in continuous use at the following mills for the periods given below: Vedras, Sinaloa, Mexico—Anglo-Mexican Mining Company, 40-stamp mill, five years; Park City, Utah—Marsac mill, Daly Mining Company, 30-stamp mill, four years; Aspen, Colorado—Holden S. & M. Co., 30-stamp "custom" mill, one year. The practical operation of the process can be easily inspected at any one of these places.

The cost of chemicals for the Russell process has averaged, on over 200,000 tons treated at various mills, less than \$1 per ton of ore, and about 65 cents per ton on 50,000 tons of tailings recently handled by the process.

The following table gives the average analysis of the ores treated by the Russell process at the Vedras, Park City and Aspen mills, illustrating the applicability of the process to ores of widely different composition:

ANALYSIS OF ORES.

NAME OF ORE.	Silica, Per Cent.	Carbonate of Lime, Per Cent.	Iron, Per Cent.	Zinc, Per Cent.	Lead, Per Cent.	Sulphur, Per Cent.	Barium Sulphate, Per Cent.	Copper, Per Cent.	Arsenic, Per Cent.	Magnesia, Per Cent.
Vedras.....	25.0	46.5	9.8
Park City.....	78.6	2.0	1.6	5.3	3.6	0.7
Aspen.....	20.9	20.0	9.1	1.5	1.0	7.5	24.8	5.8

It has also been demonstrated in the case of various ores which have been treated by this process, in amounts varying from 1000 to 40,000 tons, that the zinc and sulphur contents of ores may reach as high as 20 per cent each, lead 15 per cent, pyrites 40 per cent, barium sulphate 45 per cent, and carbonate of lime 45 per cent, without materially increasing the cost of treatment or decreasing the per cent of gold and silver extracted by the Russell process.

By an entirely wet method of parting and refining, recently invented, the product of the Russell process is now treated at each mill, and the gold and silver recovered separately as fine metals, subject to no further parting or refining charges. This method is simple, and the cost very low.

As compared with smelting, in the case of the ore treated at the Marsac mill, the net profits are in favor of the Russell process by about \$250,000 per year.

A comparison of the Russell process with the Kiss, Patera

or old leaching process, as determined by four comparative mill runs, of one to three months duration each, made at Vedras during the last five years, shows that the Russell process extracted 16.5 per cent more of the value of the ore at \$6 to \$7 more net profit per ton, averaging, at the rate of 13,000 tons, \$86,000 net profits per year, over the other processes.

As to the comparison of the Russell process with amalgamation, as illustrated at the Marsac and Ontario mills, in Park City, Utah, the following statement gives a summary of the results on the ore treated in each mill during 1891:

To treat the same number of tons, 25,000 per year, of approximately the same composition as at the Marsac, the Ontario (amalgamation) requires 45 per cent more power, 39 per cent more labor, 30 per cent more stamps, 100 per cent more furnaces, 48 per cent more salt, and 40 per cent greater cost of chemicals, and yet yields a less per cent both of gold and silver than the Marsac mill using the Russell process. These differences foot up a total saving of \$91,000 per year in favor of the Russell process.

The treatment, at the rate of 50 tons per day, of old tailings at Vedras, by the Russell process, has yielded for three years a net profit of \$21,000 per year.

The exact figures on the extraction of gold by actual "clean up" in the above two mills show that for 1891 the Russell process extracted 25 per cent, and for 1892, 24.3 per cent more of the total gold in the ore than was extracted by amalgamation.

Specifications for Roads.

The Supervisors of Marin county have advertised for bids under the new road law for keeping the roads in order. The bids are asked for by districts, and the number of miles in each district is given. Following are the specifications:

All roads to be kept in a safe and passable condition at all times; to be kept well rounded up in the center with the best material to be had, so that water will not remain on any of the traveled portion thereof; to be properly ditched and drained, and all culverts must be kept open for the free passage of water, and in good repair; repair all bridges and culverts, and renew or rebuild any bridge or culvert under sixteen feet span; keep the traveled portion of the roads cleared of all brush or branches that would interfere with the comfort and safety of ordinary travel; keep all the roadways clear of thistles and cockleburrs.

THE general sentiment in favor of better roads has led Congress to take action in recognition of it. There are two bills looking to the awakening of the people generally on this important subject. One appropriates \$10,000 to enable the Secretary of Agriculture to make inquiries in regard to different systems of road management throughout the country and to make investigations in regard to the best methods of road-making. Also to prepare a publication on the subject suitable for distribution, and to enable the Secretary to assist agricultural colleges and agricultural stations in disseminating information.

STATE SENATOR MCGOWAN thinks legislation in fences is needed. He has introduced a Senate bill defining lawful fences as follows: If made of stone, 3½ feet high, 3 feet at base and 1 foot at top. If a worm fence, to be well laid and 5 feet high. If of posts and boards, posts not more than 8 feet apart, and if intended to turn all stock, five boards, 6 inches wide; if nest cattle, horses and mules, three boards, the top at least 4½ feet high. If made of pickets, posts and rails, ditch or ditches, wire, hedge brush, or other material, the fence must be equally strong and secure as that of posts and boards.

JIM MASON, Thomas Breen and a Finn whose name could not be learned, who were employed in the Rapid River Mining Company's camp in Idaho county, started for Lewiston, Idaho, with pack-horses to purchase provisions, which had run short. The trail to Lewiston runs through a very mountainous country, which is as yet entirely unsettled. After the men had left a severe snow-storm set in, which later developed into a blizzard, and the cold became intense. Searching parties failed to find the miners, who doubtless perished from the cold.

CALIFORNIA ZOOLOGICAL CLUB.—At the annual meeting of the California Zoological Club, the following officers were elected for the ensuing year: Dr. J. G. Cooper, president; Dr. Gustav Eisen, vice-president; Miss Effie A. McIlriach, secretary; T. S. Brandegee, treasurer; E. C. Van Dyke, curator. Councilors—Miss Emily I. Wade, Will W. Price, Miss Lillie J. Martin, Charles Fuchs. Dr. J. G. Cooper delivered an interesting lecture on "The Shells of the Gulf of California," showing hundreds of specimens.

GEOGRAPHICAL SOCIETY OF THE PACIFIC.—Officers elected at the Council Meeting of January 31, 1893, to serve one year, are as follows: President, George Davidson, Ph.D., Sc.D.; 1st Vice-Pres., Th. E. Slevin, L.L.D.; 2d Vice-Pres., Hon. Ralph C. Harrison; 3d Vice-Pres., Irving M. Scott, Esq.; Treasurer, H. Durbrow; Home Corresponding Secretary, Hon. Jeremiah Lynch; Foreign Corresponding Secretary, P. W. Poulson, M.D.; Recording Secretary, John Partridge; Assistant Recording Secretary, T. F. Trenor, M.A.

JOHN MCFARLANE was instantly killed in the Ontario mine, Park City, Utah, on Sunday. He was working in a slope fifteen feet below the six-hundred level, when, without warning, the ground gave way and he sank with it to the seven-hundred level, timbers, earth and all going down in a confused mass. The vein is very wide at that point and the walls are smooth, which probably rendered the timbers unable to hold the weight.

Our Animal Industries.

We are glad to see that the annual report of the State Board of Agriculture, presented at the annual meeting held last week in Sacramento, places full emphasis upon the importance of the animal industries of the State and the field which invites their extension. Other matters are, of course, duly considered in the report, but these other matters, notably the fruit products, are constantly before the public eye and do not lack appreciation. The State Board of Agriculture has a plain duty to perform in securing for the animal interests such recognition as their importance and their possibilities merit. If the State Board could go even farther in this direction than it has hitherto, give the road and field qualities of the horse greater prominence in its efforts and add thereto the publication of useful reports upon the most successful lines of livestock-breeding and care, veterinary practice, etc., under the conditions which prevail in this State, the State society would have a more general support and a better reputation throughout the farming regions of the State. It plainly recognizes the importance of such things and will, we hope, accept our suggestion that it go farther in their pursuit.

The report to which we allude makes an interesting generalization on the standing of California in the blood-horse world, which we quote as follows:

The great battles for supremacy waged under the auspices of this society right here at home encouraged our breeders to go forth and meet the world with their products, and the result is that one of our great sires has, during the season just closed, achieved a world-wide reputation by having eight of his get obtain records of 2:15, or better, and only second in the list of money-winning sires of America. Another mighty sire obtained the world's stallion record, so that California has at this writing the fastest individual stallion of the world; the sire of the greatest number of extreme speed performers in the world; the sire (recently dead) that produced the greatest number of horses with trotting records of 2:30 or better; the largest thoroughbred stock farm in the world, and last, but not least, the highest-priced thoroughbred stallion in the world.

When we state as a fact that this State annually sells the greatest number of thoroughbreds in the New York market that comes from any one breeding farm, amounting in the aggregate to \$120,000, and that the sales of trotting stock aggregate \$500,000 yearly in the same market, and that California sales here at home of improved-bred stock reaches \$300,000 per annum, making an aggregate of nearly \$1,000,000, can it longer be doubted that the interest in question is of some importance to California?

This is certainly a most gratifying showing in that line of effort. Even those who believe other lines of work are more important will grant that. But the State Board is also cognizant of other lines which need promotion. The report earnestly favors more systematic and comprehensive work in the live stock interest on the part of the general Government. It approves the tendency toward the building up of great slaughtering enterprises here and the systematic extension of the local production of cured meats and the utilization of all the by-products of the abattoir. The local field for such work is notable. Our importation of hams, bacon, lard and canned meats each year from the factories of the Western and Middle States is of such magnitude as to cause one not informed to doubt the figures. There was an average of six carloads of ten tons each per day for every day in the year 1892 brought from across the Rocky mountains. To make up a home product to cut off this importation we have our vast area of alfalfa lands and our grain fields, which sadly need a better outlet than now exists for wheat.

In the dairy line, too, there is room for considerable extension if marketing is so ordered that the genuine shall not be depressed by the spurious. No country has the forage facilities for producing milk equal to ours, but we cannot increase our dairy facilities and import from 600 to 1000 tons of condensed milk into the State each year. The quantity of this great commodity used within the State, to say nothing of that needed for the territory of the Northwest and countries that lie adjacent to be furnished by ship cargo, makes it a plan most feasible at this time. There is no reason why, with our cheap forage facilities, we should not control this business for the entire country west of the Rocky mountains.

The San Francisco market alone consumes the milk of from 10,000 to 15,000 cows in their use of butter and fresh milk for daily delivery. Still we import from 2000 to 3000 tons of packed butter each season. We are thus situated, and abide the coming of others to profit by the indifference of our own people in the formation of a stock company for the development of this dormant resource.

We are glad the State Board has thus prominently called attention to these matters. It is clear that all who seek investment in California production need not follow fruit lines. It would be far better if they should turn their effort and capital into other channels. Conditions favor such investment. There is abundant suitable land available at low prices. Pure-bred cattle of all kinds were never cheaper, and one can begin with the best blood for a fraction of the cost which would have been required a few years ago. We long to see more of this State in alfalfa. We would enjoy more breeding farms and dairy buildings. We are not afraid of the outcome of the fruit investments at all, but it will make these investments all the more secure and would stimulate activity and prosperity in all other industrial lines if the animal, as a basis of intelligent and progressive production, should receive wider attention at the hands of our people.—*Pacific Rural Press.*

A BILL of considerable importance has been introduced in the legislature by Raw, of El Dorado county, adding a section to the exercise of the right of eminent domain. It adds canals, ditches, flumes, aqueducts and pipes for supplying water for operating machinery for the purpose of generating electricity for the supplying of mines, quarries, railroads, tramways, mills and factories with electrical power, and also for supplying electricity to light mines, quarries, mills, factories and incorporated cities.

Mechanical Progress.

New Textile Mills.

The report upon the textile industries in 1892, which has just been published by the *Textile World*, exhibits a condition of industrial prosperity which must be highly gratifying to anyone interested in the welfare of the United States. According to this report, the accuracy of which cannot be questioned, there were established during the year 272 new mills, employing 31,500 persons. Of these mills 73 are devoted to the manufacture of cotton, 49 to woollen, 93 to knitting, 21 to silk, six to plush, three to linen, three to lace curtains, two to jute, four to chenille goods, six to shoddy, seven to cotton-bating and five to dyework and bleaching.

Of the 73 new cotton mills 19 were built in Massachusetts alone. These 19 mills contain 474,000 spindles, 8835 looms, and give employment to 5775 persons. The size and importance of these mills are best seen by comparing them with the mills built at the south during the same time. In the States of Alabama, Georgia, North Carolina, South Carolina, Texas and West Virginia, there were erected in 1892 a total of 39 mills, or exactly 20 more than in Massachusetts, or one more than twice as many, yet the 19 Bay State factories operate 474,000 spindles and 8835 looms, while the 39 Southern mills operate only 251,800 spindles and 5851 looms. The employees in the new Southern mills exceed those in the new Massachusetts mills by just 20.

In the woollen industry there have been established 49 new mills, of which 22 are in New England. Of the latter, eight are in Massachusetts and seven in Maine. The increase in the producing capacity of Maine was especially noticeable, as nearly one-third of the entire increase in the United States was furnished by this State.

A total of 93 knitting mills were built, 20 of which were in New York and 32 in Pennsylvania. The new silk mills started numbered 20, which, together with the greatly increased importation of raw silk and the great decrease in the importation of the manufactured article, shows the new start this industry has taken in America. In no other year has the United States shown so great progress in the textile industries.

Determining a Steamer's Speed.

The reports so far made public with regard to the performance of the U. S. practice cruiser Bancroft are exceedingly favorable to that vessel and creditable to her builders, the Samuel L. Moore & Sons Co. of Elizabethport, N. J. It will be remembered that we have quite fully illustrated this vessel and her machinery, and it is gratifying to know that upon trial she has proven her ability to so far exceed the contract requirement of 12 knots per hour as to make it probable that her builders will receive as a premium about \$45,000 above the contract price. The method of determining her speed is a new one, which has been introduced by Chief Engineer Commodore Melville, and consists essentially in first standardizing the screw, this being done by running the vessel over an accurately measured mile course, and making careful comparisons between the observed speed of the vessel and the number of revolutions made by the engines. By a series of such observations, the ratio between the rotative speed of screw and the rate of the vessel is definitely determined, and then, during the four-hour run at sea, the speed of the screw, or the number of revolutions made by it, are taken as indicating the speed of the vessel. This transfers the actual measurement of the speed of the vessel from the conditions where it is almost impossible to determine this accurately to conditions where it is quite possible to determine it with the greatest precision, and it is reasonably certain that a given speed of screw will produce a given speed of the vessel, this having been pretty conclusively shown by the experience of the engineers of transatlantic steamships, who declare that under ordinary conditions they can tell, with considerable accuracy, how near they may be to port, by looking at the revolution counter at any time, and that the total number of revolutions during a transatlantic trip varies surprisingly little.—American Machinist.

TEMPERING.—A new process of tempering a 14-inch Harveyized armor-plate was tested at Bethlehem on January 16th. Heretofore this was done by ejecting ice-water against the red-hot plate, in a vertical position, with the result that the water was made boiling the instant it touched the upper end of the plate, and the heated water running down did not have the proper effect

on the rest of the plate. In the new process the plate was laid down in a specially-prepared frame; the water was made ice-cold by treating it with salt, and was then led to a large sprinkler lowered within one foot of the plate. The water was forced through the sprinkler under great pressure, while the under-side of the sprinkler was kept cool by water running over it from a fixed spigot. The sprinkling continued for 1½ hours, and the plate was then taken up by a crane and immersed in the oil baths there, to remain 30 hours. The Government officers present regarded the new process as highly successful.—Engineering News.

Horse Power.

So much ignorance exists as to the meaning of the words which head this article that we have thought that a few practical words on the subject may prove of some service to our nontechnical readers, of whom we are pleased to know we possess an exceedingly large number—especially abroad. We may commence, then, by pointing out that if the boiler is new, or has never been tested, the heating surface is the best guide to a knowledge of what it will be capable of doing. If the boiler is well designed and properly set, two pounds of water should be evaporated for each square foot of heating surface, so that, on a recognized basis, 15 square feet of heating surface should be allowed per horsepower, and in estimating the horsepower of a boiler the external surface of that portion of the shell which is exposed to the fire should be estimated, and to this, expressed in square feet, should be added the area of the tubes, and of such portions of the heads as are exposed to the direct heat. The sum should then be divided by 15, and the result is the nominal horsepower of the boiler. This rule is not absolute, but, like all other rules, it has exceptions. With the most approved settings, and with well-managed fires, the evaporation is greater than that estimated above, and we find that in such cases 12 square feet of heating surface will evaporate the quantity of water required for a horsepower. In some exceptional cases the requisite heating surface is even less than 12 square feet, but we do not use less than 12 unless we have satisfied ourselves, by careful experiment upon similar boilers, similarly set, that we may do so fairly. On the other hand, if the boiler or the setting is poorly designed, or the draught more imperfect, or the fires badly handled, more than 15 square feet may be required. There is no such thing possible as an absolute rule for the horsepower of a boiler, and the rule we have above merely represents what, in our experience, a given boiler, well designed, may be expected to do under ordinary circumstances.—Machinery.

Effects of Pickling Iron.

The effect of pickling and rusting on the strength of iron has been shown by A. Lelebur, of Berlin. Rails, joists and bars were subjected to various conditions: (1) in the condition as delivered; (2) after exposure for purposes of rusting; (3) zincd (galvanized) and tested at once; (4) galvanized and exposed for a time; (5) pickled in acid and immediately tested; (6) pickled and kept for a time in a dry place. The pickling was done with sulphuric acid diluted with water in the proportion of 1:100. The samples were tested for transverse, tensile and compressive strains, and under a falling weight, these experiments being made on the same sample for each of the six conditions. The bending tests with wrought iron joists showed substantially the same for all the conditions; the maximum loads carried showed differences, being highest in the natural condition and lowest when freely pickled. Rusting also produces a diminution of strength more apparent in the galvanized than those not galvanized. In the instances where the specimens were broken, the diminution is said to be very decided in the pickled and perceptible in the rusted specimens. The figures are: breaking strain under condition 1, 35 tons; under condition 2, 33.9 tons; under condition 4, 32.7 tons; under condition 5, 29.6 tons; under condition 6, 30 tons. The steel specimens showed results which follow the same law.

ENGINEER J. H. JONES, of the North Pacific Coast Railway steamers, when having the boilers of the steamer San Rafael overhauled last year, had a kind of pocket built on the inside of the main shells at one side, into which the feed water is pumped, and from which the sea blow-off leads out. This pocket consists of a sheet about three feet wide flanged at the sides, and riveted to the main shell inside, leaving an annular space around the side of the boiler, 30 x 2½

inches, the top or overflow being a little higher than the flues. The area of this chamber being about forty times that of the feed pipe, the water injected rises slowly, is thoroughly heated, and precipitates nearly all of any mineral substance it may contain before reaching the main body of water in the boiler. Several times each day the blow-off valve is opened for ten seconds or so to keep this intake chamber clear. A hand-hole is provided for inspection, and the cost of the whole was about \$35 on each boiler of 300 horsepower. The idea is neat, effectual and inexpensive.—Industry.

Scientific Progress.

Saltiness of the Sea.

Professor Edward Hill read a paper before the Victoria Institute recently on "How the Waters of the Ocean Became Salt." From an inquiry into the character and affinities of the organic forms of the past geological ages, the conclusion was justified that the waters of the ocean must have been salt from very early geological times, but it by no means followed that they were as fully saline as those of the present day. There were two ways by which they might account for the salinity of the ocean waters from very early periods of geological time. First, by supposing that the primeval waters were saturated with acid gases which were held in suspension in the vapor surrounding the incandescent globe; or, secondly, that the salinity resulted from a process resembling that by which salt lakes of the present day had been formed. He thought that they must concur with Dr. Sterry Hunt that from some cause or other chlorine largely abounded in the waters of the primeval ocean, as by far the greater proportion of the salts were chlorides and chlorine was very slightly represented in river waters of the present day.

From the example of closed lakes they could determine the process of salinification with the utmost certainty. Throughout greater or shorter periods these lakes have been receiving the waters of rivers bringing down both mechanically suspended sediments and chemically dissolved salts, silicates and carbonates. The sediments were precipitated over the bottoms of the lakes, and the water, being carried off into the atmosphere in the form of vapor as far as it entered, left behind the dissolved ingredients. These necessarily augmented in quantity, and ultimately the waters of the lakes became saturated with salts and carbonates, which were then deposited. The ocean was a closed lake of enormous magnitude, and they were thus brought to the conclusion that the saltiness of the sea might have originated in very much the same way as had that of the Dead Sea, Lake Urmiah, or the Great Salt Lake of Utah, and many others which possessed in common the characteristic of having no outlet. When the great envelope of vapor which surrounded the incandescent globe began to condense upon its cooling surface, the resulting waters, though containing, as Dr. Sterry Hunt supposed, acid gases, were destitute of saline ingredients. The process of salinification began with the first streams which entered the seas from the bordering uplands, and this process carried on throughout the long ages preceding the silurian period, brought the waters to a condition suited to sustain the life of forms of inhabitants representative of those which inhabit the ocean at the present day. These long ages might be supposed to include not only the archæan and æzoic periods, but that in which the first crust was in course of formation over the incandescent globe.

Heat Storage.

Professor W. C. Unwin, in the course of a lecture, delivered at the Society of Arts last Friday evening, drew attention to a means of storing energy, which, if it fulfills all that is claimed for it, may prove of great service in electric-light central stations. In this system the energy is stored in the form of superheated water kept under pressure, in boilers specially covered with nonconducting materials in order to minimize the loss or heat from radiation. When the energy is required the pressure is taken off the superheated water, and it at once turns into steam; when energy is being stored, the pressure is again increased.

Judging from the results already attained with this system, it is possible to store large quantities of energy in a comparatively small space, in a convenient manner, and at a cost far below that of storage batteries of equal capacity. If experience shows this to be really the case, it will result in great economies being effected in the maintenance of

alternate-current central stations. They will then be able to compete on favorable terms as regards storage, and the cost of production per unit, with continuous-current ones, and one of their chief sources of loss will be eliminated. We await with much interest further information on this most interesting and important subject.—Electricity.

XYLOLITH.—A new material manufactured in Germany and called "xyloolith" ought to be valuable for use in lagging steam-boilers and steam-cylinders, if all the properties claimed for it can be substantiated. The name is from two Greek words respectively meaning wood and stone; from which it may reasonably be inferred that it partakes of the nature of both the materials from which the name has been suggested. It is made of sawdust by treatment with some ingredient or ingredients, the process being a secret with the manufacturers. Its leading properties, which seem to peculiarly fit it for insulating purposes, are stated to be noninflammability, nonconducting power, imperviousness, freedom from shrinkage, and susceptibility to a high polish. These properties, added to the fact that it is cheap enough to compete with wood in architectural uses, are just the requirements for steam lagging, and there appears to exist no mechanical difficulty in applying it to this use, since it can be worked like wood, according to descriptions of it that come from apparently reliable sources. Whether it is really superior to sawdust compositions of American manufacture that have been put on the market only a competitive trial can determine; but its qualities, as described, appear to be quite different, it being harder and stronger, and capable of being polished.—Engineering Magazine.

WATER IN PLANTS.—A problem familiar to all students of botany is that relating to the ascent of water in plants. Text books explain the phenomenon in more or less plausible ways, and doubtless it may be news to many to be told that they knew nothing about it. The latest, and perhaps the most thorough investigation in this direction, is that by Prof. Strasburger, of the University of Bonn. The evidence all appears to favor the conclusion that the ascent of water in plants is a purely physical process. That it is not a vital one was proved by the ability to cause an upward flow in plants previously killed by various methods. The conditions necessary for the ascent of liquid are stated to be that the cell walls should be in a state of imbibition, while the tracheæ are within certain limits filled with water and isolated from the air. The learned professor definitely disposes of some time-worn explanations when he states that atmospheric pressure simply helps to keep the water suspended, that the only importance of transpiration in this connection is that it makes room for the ascending fluid, and that root pressure is not immediately concerned in the process at all. Capillarity has long been known to be insufficient to account for the phenomena, and the net result of the research is that we are left in the position of knowing nothing whatever concerning the cause of sap in plants, save that the process is a purely physical one.—Scientific American.

VEGETABLE GROWTH IN WATER MAINS.

—A vegetable growth in the water mains at St. Paul, Minn., has lately, according to the *Engineering Record*, been the cause of some trouble. The first case was discovered by the superintendent, in one of two service pipes in a single trench supplying a double house. A complaint was made of bad water, which flushing failed to improve. One of the pipes delivered pure water and one supplied a muddy liquid that was of no use. This fact led to the conclusion that one of the services was foul; and the remedy applied on this supposition proved effective. The boiler of a portable engine was connected with the faucet of the kitchen sink from which the muddy water came, and a steam pressure of 70 pounds forced against the 35 pounds water pressure for 30 minutes—thereby driving the water out of the pipe. Since that time the pipe has always delivered clear water, and twelve similar cases have been successfully treated in the same manner. Great care has to be taken that there are no leaks in the service pipes, and that none of the fittings are open during the steaming process.

HOW TO FREEZE WATER ON A SMALL SCALE.—Take a concave watch glass, touch the convex side upon water so as to leave a drop hanging on the glass. Pour a little ether into the concave and blow upon it. The rapid evaporation of the ether will render the glass so cold that the drop of water will be frozen.

Electricity.

Storage Batteries in Electric-Light Stations.

The annual report of R. R. Bowker, first vice-president of the Edison Electric Illuminating Company of New York, is a very complete one, and full of interesting matter. In regard to the experiments now in progress by the company with a view to determining the commercial value of storage-battery installations as auxiliaries to regular dynamo plants, Mr. Bowker says:

"The general use of storage batteries in connection with station work in England, France and Germany, as seen during my investigations abroad, made it seem advisable to experiment with a storage battery of a type in successful operation in England, which would not be complicated with the legal questions involved in the batteries hitherto known in this country. Arrangements were therefore made with the Crompton-Howell Storage Battery Company, Limited, of London, to install in a portion of our new 53d-street station, arranged for that purpose, a storage battery of 2000 ampere-hours capacity, on which guarantees of 85 per cent. efficiency in ampere output and other guarantees were obtained. This battery is now installed at that station and will presently be working as a part of our operating system, and its results during the experimental period of six months will throw much light on a problem of very large importance to this company as well as to other Edison low-tension direct-current systems throughout the country. After this battery has been in operation for a sufficient period to demonstrate its advantages and disadvantages on this company's system, it is intended that the general operating superintendent shall give attention while abroad to the actual workings and economies of the storage batteries of the various types in use in England and on the continent. It is still an open question whether a storage-battery plant, which cost in round numbers about twice as much as a generating plant of an hourly capacity equaling the total-charge capacity of the battery, can be economically utilized on a system so large as that of this company, requiring continuous operation in at least two of its stations throughout the twenty-four hours. On the other hand, the storage battery, with the addition of a 'booster' or motor dynamo for automatically raising voltage, developed by Mr. Barstow, of the Brooklyn Edison Company, should be of considerable use to this company in developing remote districts not yet ready for station equipment, if not for increasing the economy and efficiency of the dynamo plant, and will most certainly be found of use in connection with smaller Edison plants whose minimum load is so small as to permit of the use of a storage battery to replace one labor shift."

Electric Motors on Steamships.

Although electricity now plays an important role on great steamships, there is, beyond a doubt, a chance to extend its use profitably. This general statement, which is perhaps somewhat trite, is suggested by the recent disablement of the Umbria on her voyage from Liverpool to New York. Every one has read how the shaft was repaired under the direction of the able chief engineer, who determined to undertake the work although his assistants considered the job absolutely hopeless. Under the most adverse circumstances, the shaft was repaired, and the ship was able to steam into New York harbor at half speed. It was a triumph of trained skill, wonderful patience and perhaps good luck. The fracture of the shaft was located at such a point that only five men could be employed at a time upon the repairs. Before the undertaking was completed and the shaft was allowed to revolve, it was necessary to drill in the aggregate 180 inches in the hardened steel. As the work was necessarily done by hand, it was a slow and tedious task. The appliances on board that could be utilized were few in number and very simple in character, according to the statement of the chief engineer. It is not expected that a well-equipped machine-shop can be maintained on shipboard, and machine tools cannot be readily employed in the confined spaces where their use might prove desirable; but it seems to us that at least one addition could profitably be added to the meager stock of appliances now carried. An electric motor could readily be moved from point to point for supplying power where it might be needed. Its dimensions are so small that it could be located wherever a man could find room to work.

All the large ships are now lighted by

electricity, so that power is always available. In the case of repairs on the Umbria shaft, a portable drill could easily have done the work of a dozen men, and have done it better. While delay apparently was not dangerous with the Umbria, still the utmost desire to complete the work was experienced even by the cool and level-headed chief engineer, who admitted that the engines were started before the fractured shaft was repaired as thoroughly as he wished. Every gain of an hour would have been worth more than the cost of a score of electric motors. While danger perhaps did not exist in this particular case, it is easy to conceive of a situation where rapidity in the completion of repairs might be essential to the safety of a vessel. The value of an electric motor for furnishing power under such circumstances cannot be overestimated. The cost of a portable electric drill or of a suitable design of portable motor for furnishing power for the numerous mechanical operations now necessitating manual labor would be nominal, while its use in an emergency could be supervised by one or two men, leaving the other engineers free to attend to other necessary work. Such an equipment, in view of the Umbria incident, should form a part of the store of tools on all the great steamers in which electric current is available.—Western Electrician.

Electrolytic Methods of Disinfection.

Mention has been made of the fact that at the time of the outbreak of cholera at Havre and Rouen the prefect of the Seine utilized electrolytic methods of disinfection to combat the epidemic, says *Electricite*. The system employed was that of Eugene Hermite, which involves the electrolysis of common salt or any other of the chlorides, producing a discoloring and disinfecting solution. The boiler and engine are located on the ground floor, while the dynamo and electrolytic bath are placed in the room above. Sea water, or a water in which sea salt has been dissolved in the proportion of 2½ kilogrammes to the cubic meter, is introduced into the electrolytic vat. Under these conditions there are formed hypochlorites, or at any rate combinations of oxygen and chlorine possessing the power of destroying malodorous products and infectious germs. This disinfecting and antiseptic solution is drawn into a reservoir, whence it is piped to the street. It is used for washing, etc.

At the present time, when matters of sanitation demand special attention, and when the problem of rendering sewerage innocuous demands solution, the electrical means of disinfection become of paramount importance. Sewage from the Paris mains is partly employed in irrigation in the plains of Gennevilliers and Asnières, on the left bank of the Seine. The system was connected in 1872, and several hundred acres are now under treatment. During part of the year irrigation is not possible, and even if it were there are still collected in these fields almost all the disease germs of the city of Paris. The land becomes then a place for germ culture, and is a constant menace of an epidemic of infectious disease. It seems to be both necessary as well as prudent to sterilize the sewage.

The several electric processes of purification will be recalled. Among others are that of William Webster, tried in England, and that of Hermite, which has for some years been employed at Rouen, with results which, if not decisive, are at least very encouraging. These processes are familiar. The sewage water, with some chloride added (common salt or chloride of iron, for example) is caused to pass through the electrolytic process. This direct means of treatment is perhaps impracticable in a city like Paris, inasmuch as the amount of sewage water reaching the collecting reservoir at Asnières ranges from 300,000 to 600,000 cubic meters daily; but an indirect method is perfectly feasible, which would consist in adding to the sewage a concentrated solution of electrolytic hypochlorite.

The problem of electrolytic disinfection becomes simple and practicable wherever sea water is procurable. On board vessels, where motive-power is available, it will be a simple matter to prepare the solution; and seaports, which are nearly always infected, can be readily supplied with this simple chlorine disinfectant. Let the sanitary commissions of ports, which so often are the starting-points of epidemics, utilize these processes, and we will no longer see cholera at Toulon or at Havre, or at Hamburg. No antiseptic can be prepared more economically than electrolyzed sea water.

WELLMACH'Y All Kinds, Water, Gas, Oil, Mining, Ditching, Pumping, Wind and Steam Heating Boilers, &c. Will give you to send 25c. for Encyclopedia, 1500 Engravings. The American Well Works, Aurora, Ill., also, Chicago, Ill.; Dallas, Tex.; Sydney, N. S. W.

Professional.

Standard Shot-Gun Cartridges.
Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Denton's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. TAYLOR, Pres.; LEONARD GOW, V. Pres.; H. A. JONES, 24 V. Pres.; P. GOW, Gen'l. Technical Mgr. and Asst. Treas.; T. L. WIGWALL, Gen'l. Mgr. and Sec'y; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
The Glasgow Works
The Cassel Gold Extraction Co.,
Limited, Scotland.
Also in Australia, South Africa,
New Zealand, Queensland, Etc.

General Office of Company:
Rooms 8, 9 & 10, Taber Grand Opera House
Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingston Gold Mining Co., Boulder Co., Colo.; The Puzzer Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champion's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned King and Last Chance Mines, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Co., Gold Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the MacArthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process.

If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 60 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubes especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ores for this process are the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,
P. O. Box 926. Gen. Mgr. and Secretary.

A new and thoroughly revised edition.—Just Ready.

THE PRACTICAL

BRASS AND IRON FOUNDER'S GUIDE.

A Treatise on Brass Founding, Moulding, the Metals and their Alloys, etc. By JAMES LARKIN, 1st Conductor of the Brass Foundry Department in the Penn Works, Philadelphia. A new revised and greatly enlarged edition. In one volume, 12mo, 400 pages. Price \$2.50, by mail, free of postage to any address in world.

CONTENTS.—Among the most important and entirely new sections of this edition of this valuable and popular book are the following: Behavior of Metals and Alloys in Melting and Concocting; Malleable Iron Castings; Wrought Iron or Mild Castings; Manufacture of Steel Castings; Casting of Brass; Casting of Bronze; Bell Founding; Chill Casting; Casting without Core; Casting on to other Metals; Casting Iron and other Metals upon Lace, Embroideries, Fern Leaves and other Combustible Materials; Some Modern Bronzes.

Descriptive circular, giving the contents of the above book, sent free to any one who will send his address. Our new revised Descriptive Catalogue of Practical and Scientific Books, 88 pages, 800, and our Catalogue of Books on Steam and the Steam Engine, Mechanics, Machinery, and Dynamical Engineering, List of Books on Electro-Metallurgy, Moulding, Founding, Pattern Making, Metal Working, etc., and other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Locomotive is Perfection.

BUILDERS OF

"Sensible" Horse-Power Hoisting Whims.

(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, on hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake wheels at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and sheaves, 1400 lbs.

Circulars giving Capacities and Prices furnished on application.

BALDWIN LOCOMOTIVE WORKS.

ANNUAL CAPACITY 1000. ESTABLISHED 1831.

STRICTURE AND URINARY TROUBLES CURED. No charge unless cure is effected. Consultation free. Call or address for pamphlet, DR. PORTERFIELD & LOSEY, 838 Market Street, San Francisco, Cal.

Miners' Consumption.

The necessity for a scientific and thorough inspection of mining methods, so far as ventilation is concerned, is forced upon attention by the alarming prevalence of miners' consumption. It is a disease of modern origin, and is believed to be due to inhaling poisonous gases, arising from the use and combustion of high explosives, in which nitroglycerin is the powerful constituent. Nitroglycerin was discovered in 1846, and has come into use in mining only within the past 25 years. Before then only black powder was used. So far as we can learn from a study of mining records or medical accounts, the disease known as miners' consumption was unknown until very lately. It is for this reason that it is supposed to be due to the gases arising from the use of nitroglycerin. To determine the truth of the claim would require a widely extended and well-directed investigation by physicians whose practice is in mining regions. Work of this kind would certainly be cheerfully done by physicians, if there were some department of the State or Government which would intelligently inaugurate it.

If it were once determined that it is due to these gases, then the problem of better mine ventilation, and the way to secure it, so that the disease may no longer murder its hundreds of victims, will be a new one for the State and mine managers to consider.

The disease is one which is closely allied to ordinary consumption, and appears to be impossible of cure. So far as we know, and so far as we can learn from inquiry, it never attacks any but veteran miners, who are naturally those who have been most and longest exposed to the influences supposed to produce it. Many a one we all know, from Gilpin, Clear Creek and Boulder counties, has gone down to death with it. It is, too, most deadly on the Comstock. Dan DeQuille writes us that "almost every week from one to three are borne to the grave on the Comstock with this disease, and at the same time reports of the death of others are constantly being received from other regions of the Pacific coast to which they have strayed after being inoculated with the seeds of the deadly disease.

"All who develop the disease die sooner or later, even though they leave off mining in any region and take up their residence in the most favored sections of the valleys of California. The fell disease goes with these veteran miners to Mexico and Peru, to south Africa, Australia and China, and lays many of them in foreign graves. Some manage to get back to their families alive, but it is only to bid them an eternal farewell, close their eyes and die.

"All these men who are dead and dying entered the mines young, strong and the very picture of robust health. Had they gone to work at farming, lumbering in the mountains or stock-growing on the plains, instead of going into the smoky depths of the mines, most if not all of them would now still be hale and strong. It is sad to see these men, mere wasted skeletons, stretched upon their beds and dying amid a whole household of young children, just at an age when they should be at the prime of life and strength. Death stalks through the dark chambers of the mines in a thousand shapes. Generally his blows are sudden and terrible. More pitiable, however, seems the living death of the doomed man lingering down to the tomb in the never-relaxed clutch of miners' consumption."

If the State has any duty to perform in the way of doing anything for miners, would it not be well to put that work into shape, and at least give us an investigation of this subject, together with others relating to the great industry which is so closely related to the health, life and material prosperity of each and every citizen? Will our legislature do anything for miners?—Mining Industry.

Output of Creede in 1892.

Creede is in reality only one year old, that is to say the actual development of the mines began in January, 1892, and with it the great boom which has only been equaled by Leadville in the rapidity of its progress. What has been accomplished in that short period, let the *Candle* tell in its very succinct and forcible style. The number of carloads of ore shipped was 3512, representing 46,155 tons at an estimate value of \$4,215,800. Since the extension of the Denver & Rio Grande railroad from Wagon Wheel Gap to Creede, completed in February, 1892, the total tonnage shipped over that line to December 31, ultimo was 45,030 tons. The average value of the Amethyst and Last Chance ores is placed at \$90 a ton. It is estimated not less than \$750,000 has been expended in prospecting for ore. Until last fall the bulk of the output was from two

mines, although twelve are represented in the final count. The Amethyst and Last Chance continue to be the largest producers. But the New York Chance by the recent discovery of large ore bodies is likely to equal the most prolific of its rivals in the quantity and value of mineral extracted.—Mining and Scientific Review.

Some Noted Australian Nuggets.

Referring to an interesting article entitled "Gold in Nature," and mentioning a nugget of 134 pounds in weight found in "South Australia" (Victoria?), perhaps a reference to some noted Australian nuggets might be of interest. Chief among these nuggets comes the "Welcome Stranger," which contained over 2300 ounces of gold, worth about £9,200, and was found on February 5, 1869, at Moliagal, near Dunolly, in Victoria. Next in rank comes the "Welcome" nugget, found on Bakery Hill, Ballarat, in the same colony, on June 11, 1878, at a depth of about 180 feet. This nugget weighed 2200 ounces in the gross, and its value was £8780. It was sold for £10,000 to a party who wanted it for show purposes, and doubtless cleared thereby the difference in cost.

It would perhaps be a little too much to say that "nuggets have family ties," but though they usually "lie low," there are at times exceptions to the rule, and when found near the surface, as in the following instances, they are not infrequently in groups. The selections referred to (found in 1870, 1871 and 1872) are taken from the record of the "Berlin" gold-field in Victoria, and do not include the many minor nuggets found in that locality.

"Precious" nugget, 1717 ounces value £6,868, Catto's Paddock, at a depth of 12 feet.

"Viscount Canterbury" nugget, 1121 ounces, value £4420, John's Paddock, at a depth of 15 feet.

"Viscountess Canterbury" nugget, 896 ounces, value £3656.

"Kum Torr" nugget, 795 ounces, value £2872, Catto's Paddock, at a depth of 12 feet.

"Needful" nugget, 249 ounces value £984 Catto's Paddock, at a depth of 12 feet.

"Crescent" nugget, 179 ounces, value £704, John's Paddock, at a depth of 2 feet.

As a rule, the richest gold-fields are not those where the largest nuggets are found, as witness the well-known Gulgong gold-field. The largest piece of gold found on this field was only 64 ounces in weight, and was so thoroughly coated with ferric oxide that the man who was forking the gravel, etc., out of the sluice-box in which it was found, was going to throw it out, but that its weight attracted his attention.

WHAT THE PRESIDENTS DIED OF.—Rutherford B. Hayes was the only man that ever held the position of President to die of heart disease. Washington expired of pneumonia, John Adams of natural decline, Thomas Jefferson of chronic diarrhea, James Madison and James Monroe of natural decline, John Quincy Adams of paralysis, Andrew Jackson of consumption, Martin Van Buren of asthmatic catarrh, William H. Harrison of pleurisy, John Tyler of a bilious attack, James K. Polk of chronic diarrhea, Zachary Taylor of bilious fever, Millard Fillmore of natural decline, Franklin Pierce of inflammation of stomach, James Buchanan of rheumatic gnut, Abraham Lincoln assassinated, Andrew Johnson paralysis, U. S. Grant cancer, James A. Garfield assassinated, Chester A. Arthur Bright's disease. He was one of three Methodists to become President, Johnson and Grant being the other two.—Columbus Journal.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.

The Patentee and Manufacturers
cordially invite miners to critically
examine and pass judgment upon
this improved system of milling
and amalgamating ores in the fol-
lowing particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with
Stamps, Ball Pulverizers or any
other ore crushing machines now
before the public.

Send for Circulars and Price List.

CONCENTRATORS

ARE OUR SPECIALTIES.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for the
space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MASON.—*Amador Ledger*, Feb. 10: Most of the people interested in the prospect on Joe Mason's ranch are from Woodbridge, in San Joaquin county. They are so well pleased with the prospect, and with the possibilities in the claim, that upon the 4th inst. those originally interested in the project met and organized a corporation, to be known as the Mason Mining & Milling Company. Jas. Perrott was elected president, Jno. Perrott secretary and treasurer, and Chas. Newton manager and superintendent. The capital stock is \$150,000, divided into 1500 shares at \$100 a share. Every share has been taken. The company's works are in Amador county, and their place of business in Woodbridge. We are told that some of the ore recently assayed went \$10 to the ton in free-milling ore and \$110.50 in sulphurets. At the mines there are 150 tons of ore on the dump, and it is estimated there are 10,000 tons in sight. The vein is 9 feet wide and 50 feet deep. A stamp-mill and other machinery will soon be erected at the mine. The directors are James Perrott, Dave Ray, Sam Woods, Robert Boyce and Wm. Huron. The owners of the Good Hope mine are arranging to put 12,500 shares of stock on the market to secure working capital. They will proceed with work at the mine as soon as the details can be arranged. The Kennedy still seems to be on the improve. Current rumor has it that that great gold-producer made a cleanup of \$72,000 last month. Dr. Boydsau, owner of the New London mine, in the Plymouth district, has purchased the old Pioneer, adjoining, and gone to work on the tunnel, with the intention of making a thorough prospect of the property.

QUARTZ MOUNTAIN.—*Amador Ledger*, Feb. 10: In the Gold Mountain mine some important changes are taking place. Mr. Palmer has been relieved of his position. The mine has closed down, and, of course, operations have ceased at the mill. Mr. Kyle has gone down to interview the owners of the mine. Until he returns nothing definite regarding the future of the property will be known. J. Dynan is still operating his hydraulic mine. The conflagration that occurred at the Gold Mountain mine resulted in the total loss of the blacksmith shop and all combustible tools, such as hammer-handles, pick-handles, etc. The bellows were also stopped, which nearly stopped operations at the mine until another could be procured. Palmer succeeded in putting up a fireproof edifice in a few hours, notwithstanding the inclemency of the weather. The mill has suspended operations for a few days until a tramway can be extended into the bowels of the mountain and a "raise" sunk, which will lessen expenses and facilitate the handling of the ore. I understand that Wm. Ford and a crew of young Americans have taken the contract to sink the Gover shaft 100 feet, and have already commenced operations.

Butte.

AT BANGOR.—*Marysville Democrat*, Feb. 13: Frank Lane returned from Bangor last evening, to which place he had gone on business in connection with the Turner Mining Company, in which he and a number of Marysvilleans are stockholders. Thus far the company have not put up any engines or machinery, but are raising the dirt by windlass and placing it on the bank. As soon as the weather clears up they will put in a large engine and works. The dirt is very rich from this mine and the shares are in big demand. The stock has cost the investors up to the present time about \$4.20 per share, and is to-day selling for \$15 per share. This mine promises to be second to none at Bangor. The Catskill, located near the Turner mine, made its weekly cleanup on last Saturday. They realized for the six days' work \$2000, it being the largest cleanup the mine has ever made. This mine is running one arrastre and old time miners say that it is one of the largest week's work ever done by an arrastre in the State. All the mines in the vicinity of Bangor are paying well, and this spring a big boom for that locality is anticipated.

Calaveras.

THE WILLOW MINE.—*Calaveras Chronicle*, Feb. 11: Active operations are to be resumed on the Willow mine, owned by S. C. Peck & Son of this place, in a few days. There is a large amount of gravel on the dumps, and it is proposed to wash the same before commencing work in the mine. We expect to be able to chronicle a big cleanup, as the gravel prospects at the rate of 50 cents to the pan.

MACHINERY.—A couple of loads of machinery passed through town Monday en route to the Moser mine, about a mile and a half from this place. The machinery was for the mill which is in course of erection at the mine, and which, we are informed, will be ready to start in about ten days. Developments on the ledge are progressing steadily, and everything at present points to a permanent and paying property.

Inyo.

FISH SPRINGS.—*Inyo Register*, Feb. 9: The miners of Fish Springs are now doing real prospecting work. John Escallon is running a tunnel along the Goldbug vein, which will compel the "bug" to render up rich treasures, should the aforesaid "bug" have them hidden at a depth from the surface. Geo. Gilliam is throwing his youthful energy into the development of one of the most promising claims in the district. Fuller & Malone are in high hopes of a Columbian Exposition stake from a mine which

they are developing. Antone Cuhaa and Upton Tracy have struck a fine body of ore in their mine, the Queen, just south of the Goldbug. Judications proclaim that this district will soon be famed abroad. Ex-Sheriff Gregg and Dick Whittaker only await the next crop of daisies to commence washing out the yellow dross at the O'Hern placer claim, southwest of the hamlet.

PINE ORE.—*Inyo Index*, Feb. 8: Some of the finest ore ever seen in any country is now being taken out of the Hirsh mine in the Inyo range. The C. & C. R. R. will soon put in a siding at the Eclipse crossing to accommodate ore shipments from this Hirsh.

Mono.

THE BODIE CON.—*Bodie Miner*, Feb. 10: During the past week east crosscut, 550-foot level, was extended six feet. Upraise, 500-foot level, was extended eight feet. Upraise from east crosscut, 300-foot level, was extended seven feet. North drift from above crosscut was extended nine feet. West crosscut, 200-foot level, Leut shaft, was extended 12 feet. There are employed 7 miners, 1 carman, and jointly with Mono 1 engineer, 1 blacksmith, 1 watchman, 1 foreman, 1 hollermaker.

THE MONO.—During the past week east crosscut No. 1, 1550-foot level, was extended 12 feet. West crosscut No. 2 from above drift was extended 14 feet.

Nevada.

TELEGRAPH MINE.—*Grass Valley Telegraph*, Feb. 10: This afternoon Morris O'Connell visited the Telegraph mine and brought some ore to town. The rock was from a depth of about 200 feet, and the ledge is about eight inches in thickness. The rock showed well in free gold, and a double handful of dirt from around the ledge prospected to the extent of \$2 in gold.

OSBORN HILL MINE.—*Grass Valley Union*, Feb. 14: The new local company which has bonded the Osborn Hill mine has about perfected its arrangements for the commencement of work, and operations will be started next week. The Osborn Hill mine has a history. It was located in 1851, and the lode is traceable perhaps farther than any vein in the district. Bean's Directory, published in 1867, said that it had turned out as much money in proportion to the explorations as any mine in the district—paying almost fabulously for years at a time when the quartz interests of the district were considered on the wane. The mine was tolerably well opened in 1852, from which period up to 1857 it annually brought its owners large returns. But after this date the putting up of costly machinery, and poor management, put the company in debt, and in 1864 it was sold to the late Joseph Woodworth, who added to the improvements by putting up a costly mill. The mine was extensively worked as late as 1867, and numerous drifts run, but the incline was not down much deeper than 400 feet, giving a vertical depth of 200 feet. The average width of the vein was about two feet. The ground finally proved hard and expensive to work and slow progress was made, and finally operations were discontinued, although the quartz was of good milling quality. This was at a time when power drills had not come into use, and high explosives were unknown. The improvements that have been made have since greatly reduced the cost of mining, and the new company will start with every assurance that the mine will again become a valuable one and a dividend-payer.

Shasta.

NOTES.—*Shasta Courier*, Feb. 11: Stewart and McTimmons have been constructing a house and making other improvements at their mine near Salt Creek in Lower Springs district. They have a shaft down about 45 feet, and the ledge which was about two feet wide at the top has widened out to three feet. The rock shows free gold and assays well. Work in the mine is considerably retarded by water in the shaft. Simoni is pegging away at his tunnel on Middle creek. We understand that he calculates to run in 800 feet from near the bed of the creek. They are in about 200 feet, but the rock is exceedingly hard and sometimes they only progress at the rate of six inches a day. The Gladstone, near French Gulch, is employing in the neighborhood of 70 men, but the mill is running on low-grade ore. The Minnesota mine on Spring creek, north of Shasta, is going to turn out a fortune for the owners, providing they can come to an agreement that will result in active work and development on the property. The tunnel being run on the ledge shows it to be six to seven feet wide, and the quartz is fairly sprinkled with gold. James Sutherland and William Emerson are running a tunnel on the old Sutherland mine on north fork of Middle creek, about half a mile from Shasta. If they strike the ledge as rich as it formerly was, they will make arrangements to run a longer tunnel from the bed of the creek to tap it at greater depth. Sunderland has a steam-power arrastre at the mine. The mining population of South Fork are all busy developing their mines or getting out ore for working and shipment. Bailout's reduction plant will soon be completed, and, with two milling plants in the camp, South Fork will be apt to step to the front as the bullion-producing district of Shasta county. Paige and Drury started up their arrastre on Middle creek the other day. They have a ledge of good rock from ten inches to about three feet wide, and a large seam of decomposed quartz and other that will average about \$10 or \$12 per ton, with enough in sight to keep the arrastre going for a long time. Workmen are still running the 100-foot tunnel on the Hidden Treasure ledge. When the tunnel has been extended that length, the management will determine whether to go on or abandon the mine.

Siskiyou.

HYDRAULIC MINERS.—*Yreka Journal*, Feb. 11: The mild weather since last Tuesday, and the

additional installments of rain and snow, have enabled the hydraulic miners to commence operations again with good success, although the cold nights occasionally are detrimental by freezing up the supply. However, the prospects for an excellent season in hydraulic and placer mining during the coming warm spring and summer months never looked better, as there is a vast amount of snow on all the mountains to serve as fountains of supply until later in the season than for many years past. The Ashland Tidings says Caven, the Siskiyou miner, who sold to the Spencer Mining Co. the property they are working near Cole's, has made another good strike within a few miles of the Spencer mine. He has a fine-looking ledge and wants \$20,000 for it. He sold the other for \$1200.

SALMON RIVER.—*Cor. Yreka Journal*, Feb. 13: Prospects of a prosperous season ahead are everywhere apparent. Mr. Frank Hickey and R. Boyd have a promising ledge on Eddy's gulch, just above the Fagnades mine. Harvey Bowerman also has a good-looking surface ledge, but merely a prospect, as he only found it a week ago. The workers in the old Knott Nothing mine have only a short distance to run to strike the ledge, which will prove beyond a doubt that the Knott Nothing country is more than surface diggings. The Ball mine is idle at present, on account of scarcity of water to run the mill. Dos & Daggett, on the old Evening Star, are running the mill on splendid rock. Golden & Evelth have struck their ledge with a lower tunnel, and found a four-foot ledge of probably \$40 rock, which makes a good mine and extends the quartz belt. John and Claus Peters are driving a tunnel on their prospect, and expect to strike the ledge before spring.

Sierra.

THE ALASKA MINE.—*Mt. Messenger*, Feb. 11: The persons who recently purchased the Alaska property have a quartz-mill rigged up and ready to run. They are all at work running a tunnel, with the view, it is said, of getting out some rock from the upper workings of the old mine. It is expected that a tunnel will soon be started for the purpose of tapping the ledge at a point far below the lowest point reached heretofore.

Sonoma.

THE GREAT EASTERN.—*Santa Rosa Democrat*, Feb. 11: The Great Eastern quicksilver mine, near Guerneville, was opened a number of years ago and has since been regularly worked, giving steady employment to 100 men the year round. The output has been over \$1,000,000. It is now thought the mine is worked out. The plant cost \$75,000 and the company is trying to dispose of it to the Mount Jackson mine, to which it is convenient, and it is to be hoped that they will sell it, and so keep up the work in that vicinity. It would be a paying investment for the Mount Jackson, as they have a good mine but no reduction works.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Chronicle*, Feb. 11: 1500 level.—We continue running water through the old stopes at different points, and continue the extraction of ore and fillings in working upward from the sill floor in the old stopes. 1600 level.—Are repairing the main south drift and the east crosscut leading therefrom to the nraise connection with the 1500 level north drift. 1650 level.—Have continued making necessary repairs to the drifts on the sill floor of this level. We continue to extract some ore from the old stopes, eight floors up in the nraise No. 6 carried up from the main north drift; also from the old stopes in working north from the crosscut run west from the northwest drift. Are making preparations to sink a winze from the west crosscut from the northwest drift. Have extracted during the week from the 1500 level stopes and 1650 northwest drift openings and raised to the surface 490 cars of ore about 490 tons. Shipped to Morgan mill 589 150-2000 tons of ore. Average assay value, per railroad car samples, \$26.38. The average assay value, per battery samples, of all ore worked at the mill during the week (415 tons) was \$22.70 per ton.

OPHE.—1465 level.—Have continued the work of cutting out a chamber in the north lateral drift on the sill floor of this level, at the point where connection was made with this drift by the nraise which was carried up from a point 99 feet below on the north side of the crosscut run east from the drift run south from the Mexican into the Opbir ground. In this chamber, when completed, an engine will be placed to run the cses which will pass up and down the nraise.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 18 feet; total length, 533 feet, in a soft vein porphyry formation, showing some clay.

UTAH.—340 level.—The south drift from the main west drift at a point 595 feet from the shaft has been extended 18 feet; total length, 82 feet; continuing in vein porphyry, clay and fine lines of quartz. The water flowing from west crosscut No. 3 shows a very little decrease.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 25 feet; total length, 671 feet; face is in porphyry with stringers of quartz.

UNION CON.—900 level.—The joint Union Con. and Sierra Nevada west drift, 900 level, has been advanced during the past week 23 feet, making the total distance west of shaft 2911 feet; face is in clay, quartz and porphyry.

BEST & BELCHER.—200 level.—During the past week the west crosscut, No. 1, started in north-west drift, 170 feet from our south line, has

been advanced 19 feet passing through porphyry and stringers of quartz; total length, 37 feet. 900 level.—West crosscut No. 3, started from top of upraise No. 1, from 1009 level, has been advanced 14 feet; total length, 133 feet; face in clay and porphyry. Also did considerable re-pairing during the week.

ANDES.—On 420 level north drift from east crosscut No. 1, north, was advanced 17 feet; total, 98 feet; face all in quartz.

GOLN & CURAY.—200 level: During the past week, west crosscut No. 5 has been advanced 20 feet; total length, 290 feet; face in clay and porphyry. On the Sntro tunnel level the joint north drift with the Savags Company has been extended to the Savage north boundary line. This work will now be taken up jointly between the Best & Belcher and this company. We are preparing to start an east crosscut to make connection with our winze, which was run on our south line from the 1600 to the 1900 level. The face of this drift is in hard porphyry.

HALE & NOBACROSS.—We continue retimbering main incline above the 400 level. Main incline.—Are making the necessary repairs. 1400 level.—Are repairing the main north drift on this level. 1800 level.—West crosscut No. 1 from the main south drift was advanced 13 feet; total length, 113 feet; face in quartz and porphyry. West crosscut No. 3 from main north drift was extended 25 feet; total length 315 feet; face in vein porphyry. West crosscut No. 4 from main north drift was advanced 18 feet; total length 157 feet; face in quartz and porphyry.

CHOLLAE.—The north drift from the south line, 550 level, is out 157 feet; face in low-grade quartz. Are retimbering the two north compartments of the main shaft above 930 level. Are repairing the east crosscut, 160 feet south of north line, 930 level.

POTOSI.—South drift, 30 feet back from the face of east crosscut from the Potosi winze, 930 level, is out 25 feet; face is in porphyry and streaks of quartz. South drift from top of raise, 1000 level, is out 117 feet; face is in vein material consisting of soft porphyry and quartz. The north drift from top of raise, 1000 level, is out 68 feet; face in quartz and porphyry containing bunches of good ore. Have finished timbering the station at bottom of Potosi winze, 1500 level, Ward shaft, and have started a north lateral drift. Extracted and sent to the mill the past week 406 tons of ore from the 550, 930 and 1150 levels. Milled during the week 350 tons; on hand at mill, 136 tons and 1250 pounds. Average battery assays, \$25.36. Average car sample assays, \$29.04. Shipped to U. S. Mint, Carson, 485 pounds crude bullion.

BULLION.—The east crosscut, 100 feet north of top of raise from east crosscut, 300 feet south of north line, 1300 level, is out 90 feet; face is in porphyry and quartz. The west crosscut from the northwest drift, 300 feet south of north line, 1800 level of Ward shaft, is out 265 feet; face is in porphyry.

APEX.—Advancing the drift in a northerly direction, parallel with the ledge. Will hire more men as soon as the storm abates. Next week will sink No. 1 winze in the ledge to give it a test.

WARN SHAFT.—The connection from the pressure pipe, 1800 level, to the blowers is about completed. The west crosscut from the northwest drift, 300 feet south of the Bullion north line, 1800 level, is out 265 feet; face in porphyry. Have finished timbering the station at the bottom of the Potosi winze, and have started a north lateral drift.

ALPHA.—The connection from the pressure pipe, 1800 level of the Ward shaft, with the blowers, is about completed.

EXCHEQUEE.—The connection from the pressure pipe, 1800 level, Ward shaft, with the blowers, is about completed.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 5 feet, through hard porphyry; total distance from north line, 47 feet.

KENTUCK.—During the week we have been raising above the seventh floor on 160 level and have extracted some very good ore. The south drift from the Jacket east crosscut on the 1100 level has been extended 21 feet; total length, 76 feet. The face is in ore assaying from \$5 to \$20 in gold.

OCCIDENTAL.—At a point in the main north drift on 750 level, 640 feet from No. 1 winze, we have started an east crosscut in ore giving fair assays. Have also started a crosscut from the bottom No. 2 winze in south drift, 750 level. The Zedig drift, Sntro tunnel level, has been advanced 11 feet, through hard porphyry; total length of main drift, 816 feet.

Tuscarora District.

NAVJO.—*Times-Review*, Feb. 10: Work for the week has been confined to the stopes above the 350-foot level.

BELLE ISLE.—Line crosscut, 250-foot level, has been extended 13 feet in very favorable-looking ground. No change to note in the stopes.

NORTH BELLE ISLE.—The stopes above the north 300 and south 400-foot levels are without material change since last report.

Ferguson District.

APRIL FOOL GROUP.—*Pioche Record*, Feb. 9: A. C. Ellis, one of the April Fool locators at Ferguson, was in town yesterday. He reports that after running 165 feet of the tunnel recently started on the Monitor claim, adjoining the April Fool on the west, the ledge opened and an ore chamber of considerable size was cut into. Since then the walls of the ledge have diverged, and in running ten feet farther, the ore body widened to eight feet and was still improving when he left. Samples taken from about four feet of the ore face carried about six

ounces, or say \$120 a ton in gold, while the remainder of the face is good silver-bearing ore assaying about 50 ounces to the ton. This ledge of the Monitor parallels that of the April Fool claim, and the discovery here is a very important one and may result in active operations again shortly in that part of Ferguson district. In the Petty Hill, south of the April Fool, some prospecting is going on. J. A. Denton and Dan Roeder each have two men at work on two separate claims, and both are said to be looking well.

Pioche District.

YUBA MINE.—Pioche Record, Feb. 9: The ore showing in the nraise from the 1300 level east, in the Yuba mine, referred to two weeks ago, continues to improve. The ore is a heavy lead galena running high in silver, and four cars of first-grade ore are out ready for shipment. Four days ago the work of opening an air passage 80 feet west of the present ore development, and on the same vein, uncovered a foot of ore of the same grade, indicating the chute to run that far west at least. On the west of the shaft the 1300-foot drift has been extended to the vicinity of the old Mazepa working shaft, back of Meadow Valley No. 5. Whether connection will at once be made or not, we have not heard.

A RUMOR.—It is rumored about, but with what certainty we are unable to learn, that work is to be resumed by the Pioche Con. Co. here shortly, and on a general scale. We sincerely hope the rumor may prove entirely true.

Willow Creek District.

ORGANIZATION COMPLETED.—Silver State, Feb. 11: The incorporators of the Caledonia Gold Mining Company completed their organization yesterday by electing T. C. Hanson president, W. H. Kimball vice-president, G. S. Nixon secretary, First National Bank of Winnemucca treasurer and C. B. Hanson superintendent. The mines of the company are located at Willow creek, where a new mill has just been completed and will soon be in operation. The owners of the property are very sanguine over the outlook, and think it will be but a short while before a large amount of bullion will be turned out, and as it will be yellow metal, there is no discount on it.

Yellow Pine District.

LOOKING WELL.—Pioche Record, Feb. 8: The latest news from Yellow Pine and vicinity indicates the feverish interest which was recently manifested in that section to be abating somewhat, though all the mining properties are looking as well and showing up as much ore as ever. The working force at the Keystone, the gold mine of the district so far, has been reduced, 60 days ago, from 20 to but 3 men, who are operating in various parts of the property. The mine itself looks as well as at any time in the past, unless it was at the time the rich pocket was struck in the first working. Ore shipments have been regularly made. Mr. S. T. Godbe, one of the owners and manager of the property, returned there a week ago last Sunday after an absence of two months, and the working force may at once be increased. Prospecting is going on in the other parts of the district, as the means of the owners will permit, and the possibilities of the district as a great ore-producer become steadily more apparent. The main object of interest is the approaching railroad from Goffs. About 60 teams and 100 men are engaged in the work. On January 22d, twelve miles of grade was thrown up and three miles of track laid, the whole work being delayed for want of materials. Water and all supplies have to be brought from The Needles, and this will have to be continued until New York district is reached, as there is no water between the two places. The contract as let requires the road to be completed to New York district, a distance of 30 miles, by the 14th inst., but from a general shortage of supplies and building material this cannot now be done. In all probability, however, this part of the line will be finished by the end of the present month. A gentleman who has just returned from that section says there is no talk there of the road being extended farther this way for the present. The 30 miles of road now in course of construction runs over a very level section of country. Only two water-courses will be crossed in that distance, and neither of these will require bridging, while the largest fill does not reach five feet. Recent reports of prospects there have resulted in an influx of men, the majority of whom are without means, and very many are doing nothing whatever.

Vanderbilt District.

OVERDONE.—Pioche Record, Feb. 8: At Vanderbilt district over 150 men have congregated. Not more than 25 of this number are working for wages, and a very large majority of the remainder are without means. The place with present prospects is said to be badly overdone, though much hope is entertained for the future. The place, though small and of recent origin, already sports two saloons and two stores. It is situated about seven miles from New York district, and 30 miles from the Nevada State line.

DAKOTA.

THE HARNEY PEAK SITUATION.—Deadwood Pioneer, Feb. 8: Another fine specimen of tin ore from the Tenderfoot mine, of the Harney Peak properties, has been placed on exhibition at Russell & Highie's. It will weigh probably ten pounds, and is very rich in black tin. Almost every day brings forth some new evidence of the richness of these properties, and accompanying reasons why the Harney Peak Company cannot be believed to have shut down because they were discouraged. And, in point of fact, the shutdown has every indication of being only temporary, an opinion which would seem warranted by the quiet advice to some of the company's best men to not be in a hurry to get away, but to be pa-

tient and await developments. These quiet hints are said to come from parties who are in a position to know what is going on, and similar words of encouragement have been dropped to some of the Hill City business men. Another favorable feature of the situation is the fact that upward of 75 men are still at work, and that the pumps are kept running in all the mines but the Coats, the pump of which, it is said, is being repaired. There are a good many who look to see operations resumed in March.

ARIZONA.

DOS CABEZAS.—Tombstone Epitaph, Feb. 11: The Cooper mill was started up last week and 25 tons of ore put through it. The tank, which was falling to pieces, has been filled with water. The mill is closed down again for an indefinite period. One of the great necessities of this camp is a large supply of water, which can be stored in the mountains with trifling outlay. Several sites are already being looked at with that idea in view. The Casey Bros. are taking out some very rich ore in their Casey mine, upon which they will realize handsomely.

IDAHO.

THE STAR MINE.—Wood River Times, Feb. 8: The Star mine promises to rank with our best producers. At present very little ore is extracted, because the shaft is being sunk and drifts run to open the mine so as to work it advantageously. But in about 60 days the workings will be connected and stopping will probably be resumed on a large scale. By that time, too, the frost will be getting out of the ground so as to admit of the construction of the concentrating-mill, and the property can then be worked for all it is worth. The present owners of the Star paid \$38,000 cash on account. A second payment of \$25,000 will be due the 7th of April. That is already provided for, and treasury stock, set aside for that purpose on the organization of the company, is offered to pay for the mill.

ORE IN THE WOLFE TONE.—T. A. Starrh, receiver of public moneys at the Hailey Land Office, recently visited the Wolfe Tone mine, on Deer creek, in which he is interested. George Symonds, Charles Hood and Pat Donohue are operating the Wolfe Tone on a year's lease, which will not expire until October 1, 1893. Going to work in the 200 level, at a point about 200 feet in, they made a 70-foot raise, 40 feet of which shows a vein of solid galena, flanked by a varying thickness of second-class ore. The galena is 5 to 12 inches thick, and the lode is six feet wide, with concentrating ore scattered through.

MONTANA.

NEAR PHILIPSBURG.—Mail, Feb. 9: In the fall of the year 1864, Dan and Sandy Brown (two brothers) and Ben Franklin, with one pack animal, cut their way up the Flint Creek canyon and camped where Philipsburg now stands for a few days' needed rest and to make the explorations customary in those days. These pioneers were in search of placer gold, but failing to find that in paying quantities on Flint creek or any of its tributaries, and finding some rich silver float, they concluded to stay with the country until thoroughly explored. That same year the Hope mine was discovered and located by these men, and the following year the Hope Mining Company came into existence, purchasing nearly all of what is now known as Hope Hill, and they have taken out over 2,000,000 ounces of fine silver, as near as can be computed; but never in the history of the company have they been so successful as they have been in the past year. The Hope ten-stamp mill is an old-fashioned, wet-crushing concern, built of stone in 1867, and yet during the month of December, 1892, it turned out about \$120,000, which amount was increased in January, 1893.

THE GRANITE was first located by James Estell, Eli Holland and Dr. J. M. Merrell, by whom it was bonded to Charles Clark. At first this great mine had many ups and downs. By the greatest perseverance and pluck of Mr. Clark, what the experts claimed was a fair granite quarry was found to be the greatest silver mine in the world, and it has yielded a total output of \$32,000,000 and has paid over \$12,000,000 in dividends, and it is to-day probably the richest mining corporation, all things considered, and has more promising undeveloped ground than any other company in the State. The Granite Company has 200 stamps with which to crush the enormous output of ore from its mines, and is now engaged in running a tunnel from Rumsey to its lower workings on Granite mountain. This will crosscut a number of veins at great depth and furnish new evidence that the Flint Creek district as a silver producer has no equal.

THE BIMETALLIC is a continuation of the Granite to the west, and the development of this mine into the great bonanza that it is can also be attributed to the masterly pluck and energy of Charles Clark. The Bimetallic has a 100-stamp mill situated at Clark, one mile and a half from the mine and one-fourth of a mile from Philipsburg, the ore being carried from the mine by a tramway. This company's total product during the few years it has been running is about \$10,000,000, paying in dividends the sum of \$2,140,000, and the mine is but partially developed.

THE TROUT MINE has produced \$1,896,293 in silver. The lowest workings in this mine are 600 feet below the surface, but no stopping has ever been done below the 500-foot level, on which level the ore bodies are on an average of six feet in width and yield an average assay of \$75 per ton silver.

THE PURITAN lies east of the Trout on the same hill, and is rapidly coming to the front as a great producer of silver. The Puritan has always been a mine from the grass roots, and yet if it had not been for the nerve and enterprise of Mr. McKechney, it would probably now be classed as a failure instead of the real bonanza

which it is, having between two levels with but short drifts fully \$50,000 in sight. This property is now in good working shape, and can and undoubtedly will be worked no matter what the price of silver is, as the vein is wide and the first-class ore is of such extraordinary richness.

THE COMBINATION MINE was discovered by Sim Shevely in 1883, and has been continuously worked by the Combination Mining Company since 1888, with one or two brief shut-downs. A 20-stamp mill reduces the ore, and the company gives employment to about 400 men, and this with the other smaller owners, leasers and prospectors incident to a mining camp, makes Combination a busy, prosperous little town, with a population larger than some counties. The company has produced since June 1, 1888, 1,194,933.19 fine ounces of silver, and the mine never looked as well as it does at present.

OTHER PROPERTIES.—There are many other very promising properties under course of development within a few miles of Philipsburg, and notwithstanding the low price and uncertain future of silver, there seems to be no let-up by owners of good-looking prospects and partially developed mines. All things considered, there never was a brighter outlook for the Flint Creek district in a mining way than there is at present, and for many, many years to come the product of her mines would support a kingdom.

OREGON.

WHITE SWAN BULLION.—Bedrock Democrat, Feb. 6: The White Swan mine is again to the front with its regular output of gold bullion. Yesterday Mr. G. S. Tarbell, manager, arrived in town and deposited in the Baker City National Bank \$6000 for shipment to the mint. This sum was the output of the White Swan mine during a period of 12 days, a part of which time ten stamps were running. Let's see; \$6000—12 day's run—Why that's \$500 per day.

MORE BONANZA GOLD.—Bedrock Democrat, Feb. 6: The Bonanza mine still proves its wealth in its continual output of gold brought to this city at short intervals, notwithstanding the hindrances and setbacks consequent upon deep snows, poor roads and scarcity of water supply to run the batteries of the reduction plant on the property. Yesterday Mr. Albert Geiser, manager of the Bonanza, arrived in the city and deposited at the First National Bank upward of \$3000 in gold bullion, the result of a short run and obstructed somewhat by the work necessary in putting in a new boiler at the mill which is now in place. The bullion will be forwarded by the bank to the United States mint to-day.

SOUTH DAKOTA.

CONDITION OF THE HARNEY PEAK COMPANY.—Black Hills Times, Feb. 9: The directors of the Harney Peak Company officially publish the following as the condition of affairs of the company: That the capital stock of said corporation is \$15,000,000, which has all been issued as full-paid stock for the purchase and development of mining property in the Black Hills, South Dakota; that the indebtedness of said company is as follows: First bonded debt and interest, \$126,970; mortgage to be secured by issue of bonds under contract \$4,850,000; current accounts, including bills payable not exceeding \$165,000, and that said company has not paid any dividends and has not yet realized any profits upon its business.

UTAH.

A BIG CAVE.—Park Record, Feb. 11: A cave of monster proportions occurred in the Ontario mine Saturday evening at 8:30 o'clock, and when the noise and confusion occasioned by the giving away of such an immense amount of earth had subsided, the miners at once began an active search for the men working in the stope adjacent to the cave. Though many narrow escapes were reported, all the stopers were found safe and uninjured with the exception of John McFarlane, of whom no trace could be found. The unfortunate man had been working in a stope about three sets below the 600 level, and as the whole works in that vicinity had been carried down, it was at once surmised that he had gone down with the avalanche and been buried alive. The cave was about 60 feet in length and extended from the 600 to 700 level, embracing a tremendous amount of waste rock and earth that had been stored away in worked-out stopes to save the expense of hoisting. The trouble was precipitated by the giving away of some timbers near the 700 level. The weight had steadily increased until it became more than the timbers could stand, and as is often the case under like conditions, gave way almost without warning. The great rush of rock completely blocked the 700 level and affected the stopes below for a distance of several sets of timbers. The extent of the cave and the damage done was at once explored by the miners, and several men were found in very uncomfortable quarters.

PARK NOTES.—Jerry Richardson closed down his concentrator in Thayne's canyon Thursday last and will not start up again until spring. Late news concerning the Daly West credits that property with improving with each day's work performed. There is now no question as to the future of that valuable property. The Silver King is now practically idle, as only a few men are being worked. Sufficient depth has been obtained on the Meers, and drifting to the vein is now being pushed as rapidly as possible. It is stoutly intimated that a big strike may be expected in this property in the near future. The leasers on the Steele group are making a good showing and the drift they are now driving on the vein looks very promising. The indications are favorable for a big strike in this property during the coming summer. The Daly West has recently encountered considerable water, and it is taxing the pumps to their utmost to keep it down. The work of driving the drift to make connection with the Daly to secure a drain through the Ontario 600 tunnel is being rushed as fast as possible.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING FEB. 7, 1893.

- 491,403.—GAS ENOINE.—J. S. Biggar, Whitesborough, Cal.
- 491,464.—SUBOICAL FORCEPS.—C. E. Blake, Sr., S. F.
- 491,269.—FRUIT PICKER AND PRUNER.—J. H. Griswold, Oakland, Cal.
- 491,172.—SUSPENDED CHAIR.—M. A. Hart, Scribner, Cal.
- 491,427.—FLY CATCHER.—G. D. Horton, Snohomish, Wash.
- 491,354.—LAWN SPENKLER.—J. Jett, Walla Walla, Wash.
- 491,358.—MAP OR CHART STAND.—J. H. Kaufman, Marysville, Cal.
- 491,194.—SEWING-MACHINE ATTACHMENT.—Rachel A. Shellard, Virginia, Nev.
- 491,384.—DAMPER REGULATOR.—P. & J. St. Mary, S. F.
- 491,396.—KILN.—P. L. Youngren, Oakland, Cal.

The following brief list by telegram, for Feb. 14 will appear more complete on receipt of mail addresses:

San Francisco.—Hans C. Behr, variable transmitting gear; Charles E. Blake, dental forceps, six; John W. Raymond, gas engine, California—George H. Abel and J. W. Bayle, Maxwell, heading and reaping machine; Peter O. Andreason, Ferndale, butter-mold and cutting machine; John E. Armstrong, Santa Cruz, latch and lock; Charles Bizi, Selma, cultivator; Frank E. Brown, Los Angeles, coffee uro or like vessel; George Diez, Santa Clara, peocil sharpener; J. E. Evans, J. Gillespie, San Jose, paper-holder and cutter; George Rice, Vallejo, horse detach; Joseph Fisher, Los Angeles, fishing reel, Washington—George A. Stine, Spokane, sod planter; William W. Swank, Seattle, car coupling.

Note.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail for telegraphic order. American and Foreign patents obtained, and general patent business, for Pacific Coast inventors transacted with perfect accuracy, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

STEP-LADDER.—Samuel R. Smith, Colusa, Cal. No. 490,991. Dated Jan. 31, 1893. The object of this invention is to provide an improved step-ladder which is especially useful for fruit-picking and other similar work, and its object is to give the ladder a firm base, any desired spread of said base, and a means for absolutely locking it at any point to which it may be adjusted.

ROPE-LEADER FOR WINDING DEUMS.—Norton H. Pine, Eureka, Humboldt Co., Cal. No. 490,934. Dated Jan. 31, 1893. This consists in a mechanism whereby a rope is caused to wind evenly from one end of the drum to the other, to prevent overriding and injury, and in an automatic means for reversing the movement of the leader upon reaching either end of the drum.

BICYCLE BELL.—Lewis E. Ericson, S. F. No. 491,012. Dated Jan. 31, 1893. This invention relates to that class of bells for bicycles or other velocipedes in which the sounding of the bell is due to frictional contact of the wheel of the machine with power-transmitting connections. The invention consists essentially in an oscillatory plate or disk carrying the striker and operating mechanism therefor, said plate or disk by its movement being adapted to throw its striker-operating mechanism into and out of engagement with the bicycle wheel to actuate it or allow it to remain at rest. This bell can be readily adjusted to the machine and thrown into or out of action with ease and rapidity.

WRAPPING-MACHINE.—Ira R. Hutchinson, Fresno, No. 490,608. Dated Jan. 24, 1893. The invention relates to that class of machines for wrapping articles of merchandise in which swinging flaps are employed to lay the folds of the paper in place about the article. The object of the invention is to provide a simple and rapidly operating machine for wrapping all kinds of articles of merchandise, but specially adapted for the wrapping of caramels.

CONTINUOUS KILN.—Peter L. Youngsen, Oakland, No. 491,396. Dated Feb. 7, 1893. The object of this invention is to provide a kiln of such construction that the heat may be advanced and the bricks or ware dried and burned in the lower part of the compartment as well as in the top part of it, a result which is found impossible in other kilns of this type; and also provide for a perfect combustion of the fuel in the bottom portion of the kiln.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on the track of the Atlantic & Pacific Railroad. They contain a first-class fisher-power engine and 45-horsepower boiler, with Ore-crusher and other machinery, Mill scales, Assaying outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESBY, 1214 Stockton st., San Francisco.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 16, 1893

Special correspondence of the New York Financial Chronicle, under date of London, January 21st, contains the following reference to the silver market.

The Silver Market.

The price of silver continues to fluctuate about 38 1/2 per ounce, and there is a decidedly better feeling in the market. The demand for India is very strong. Very large amounts have been sent thither during the past few weeks, and the Indian banks are now buying even for a fortnight forward. The India Council, too, is selling an exceptionally large amount of bills; indeed, its sales are larger than they have been in January for eight years. On Wednesday of this week as much as 55 lakhs were disposed of. The firmness is largely due to the interruption of mining and railway communication in the United States through the bad weather, and to the hope that the Sherman Act will not be so soon repealed as was feared.

The journal above mentioned contains a review of the world's gold and silver production for a series of years. The most significant point deduced from the facts presented is that the price of silver has dropped low enough to affect the yield, and that the final summing up for 1892 will show a falling off for production in the United States. The Chronicle thinks there is pretty conclusive proof that silver production in the United States has reached a point where the average mine in all the States has become unproductive, and that under the present quotations for bullion "our contributions hereafter will be a declining factor in the world's aggregate supply." Continuing, the same journal says:

Of course, it is possible and even probable that there will be rich districts discovered and new veins struck in the future; but the silver-bearing sections have now been so searched over by individuals, cut through by railroads, and forced to their production by modern methods and appliances, it is reasonable to anticipate that hereafter new discoveries will grow more and more infrequent, and new methods of mining and refining by a very temporary resource for increased production.

The World's Gold and Silver.

M. L. Muhleman, acting assistant treasurer of the United States Sub-Treasury in New York, is credited with the following statement of the quantity of gold and silver in the world on the 1st of January:

	Gold.	Silver.
France.....	\$1,000,000,000	\$700,000,000
United States.....	650,000,000	590,000,000
Germany.....	530,000,000	145,000,000
Great Britain.....	510,000,000	110,000,000
Russia.....	280,000,000	60,000,000
Italy.....	120,000,000	60,000,000
Spain.....	100,000,000	125,000,000
Austria.....	75,000,000	100,000,000
India and China.....		1,790,000,000
Totals of above.....	\$3,265,000,000	\$3,390,000,000
Other countries.....	635,000,000	310,000,000
Aggregate.....	\$3,900,000,000	\$3,900,000,000

The above is said to be a conservative estimate. We are not so certain about that. Apart from the money actually in Government vaults and in the banks, it is a difficult question to state the amount in any country. The silver is put in at its parity with gold on the basis of 60d per ounce, whereas it is worth less than 40d per ounce from a commercial standpoint as measured in gold. It is a little singular that the metals should be so accurately divided. The amount credited to the unspecified countries includes Belgium, Holland, the Scandinavian Union, Switzerland and Austria.

Mining Share Market.

This has been a very dull week in mining share circles, business being light and prices low. The principal matter of interest in connection with the Comstock situation is the meeting held on Wednesday to talk over the proposition to pump out the lower levels. Those present were John W. Mackay, D. O. Mills, J. L. Flood and Samuel L. Jones. It is stated that they practically agreed to start pumping again. Mr. Mackay said: "The subject has been under discussion for some time, but no definite plans put forth. It is a gigantic undertaking and would require a vast outlay of capital, and before it is finally decided upon we must be sure of our ground. In a few days there will be a meeting of those most interested, and at that time it is more than probable that something will be finally done looking toward the reopening of the great mines."

It is understood that the project as outlined is to pump out the lower levels and undertake the further development of the properties lying along the slope of Mt. Davidson.

The upper drifts have all been pretty generally worked out. At the bottom of the huge shafts the water has been allowed to accumulate, and as it is in that direction only that further discoveries can be hoped for, the men who have the controlling voice have about decided to make one last effort, knowing that another strike would not only bring back to the mines the old value but would give to Virginia city a new lease of life. In order to accomplish the task, of course, a great outlay of capital would be required and the chance of failure risked, but engineers who have looked into the matter are of the opinion that there is every chance for the uncovering of another bonanza something like the one of 1874. They confess that it is the only chance to make the mines prosperous again, and for that reason they are apparently willing to make the venture.

William S. Lyle, one of our old and best-known mining operators, has resigned as president and director of the Peerless, Crocker, Weldon and other Qujiotoa mining companies with which he has been connected since their organization, and also intends to resign as director of other mining corporations in the Nevada block. Mr. Lyle says he has done this so as to devote all his time and attention to the development of a group of valuable gold mines in Vanderbilt district, San Bernardino county, in which he and other large capitalists are interested. It is understood that these properties are under the patronage of the bonanza firm. The best wishes of a host of friends will go with Mr. Lyle in his new undertaking. George Wallace has been elected president of the Qujiotoa companies to fill the vacancy caused by Mr. Lyle's resignation.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

SOLIO GOLO M. Co. Capital stock \$10,000,000. Directors: Martin White, W. C. Taddfield, F. Stadelidt, Jr., John M. Klein and E. C. Weber.

ALASKA PACKERS ASSOCIATION. The object is to catch, can, pack and salt fish in Alaska. The principal business of the corporation is to be transacted in this city. Directors: Sidney M. Smith, Henry F. Fortman, S. B. Peterson, E. B. Pond, George W. Hume, Charles Hirsch, E. B. Beck, Isaac Liebes and H. A. Williams, all of this city. The capital stock is \$5,000,000, divided into 50,000 shares.

GERMANIA INVESTMENT ASSOCIATION. Object, to encourage the systematic saving and investment of small sums. Directors: F. J. Hund, Arthur C. Drewitz, Julius Sievert, C. C. Henke, Henry Franzen, Otto A. Deicke, P. G. G. Kunze, August Birch and Charles Streich-r. Capital stock, \$1,500,000, divided into 5000 shares.

HUME CANNERY AND TRADING CO. The company is authorized to do business in California, Oregon, Washington and Alaska, and will engage in the canning of fish.

The capital stock is \$100,000, of which \$95,000 is fully paid up. The principal stockholder is R. D. Hume of Gold Beach, Washington, who holds 74-000 of the stock.

ALHAMBRA SHOE MANUFACTURING COMPANY, Alhambra, Los Angeles county. Capital stock, \$25,000. Directors—Milton Johnson, G. B. Johnson, F. E. Gray, J. M. Elliott and J. A. Green.

CALIFORNIA FISHING COMPANY. Capital stock, \$50,000. Directors—W. C. Knox, C. J. Webster, Frank Piper, G. C. Knox and George H. Perry.

CALIFORNIA GRAPE FOOD COMPANY. Capital stock, \$100,000. Directors—R. E. Wood, S. M. Tomblin, R. W. Gaff, G. C. Pratt and Seth Mann. GAVER CREAMERY COMPANY, Valley Ford, Sonoma county. Capital stock, \$5,000. Directors—A. P. Gaver, John Robertson, Walter Jones, H. M. Le Baron and C. Gambini.

THE HUMALOT ELECTRIC LIGHT AND POWER COMPANY, Eureka, Humboldt county. Capital stock \$50,000. Directors—James Armstrong, Josiah Bell, S. A. Vance, J. M. Melindy and William V. Cockwood.

CALIFORNIA STARCH COMPANY, Petaluma, Sonoma county. Capital stock, \$20,000. Directors—J. M. Striening, E. C. Austin, John Burkart, H. I. Summerhayes, W. J. Adams, W. S. Pierce and F. A. Wickersham.

RED POINT GOLD MINING COMPANY. Capital stock, \$1,000,000. Directors—I. M. Requa, J. H. Smith, F. H. Hall, G. C. Hickox and H. M. Campbell.

COPELAND PACIFIC TANNING COMPANY, Anderson, Shasta county. Capital stock, \$300,000. Directors—John W. Copeland, Isaac Atwood, S. E. Smith, Robert D. Baird and Thomas B. Smith.

THE largest cannon manufactured by the great German gun-maker, Krupp, it is reported, weighs 270,000 pounds. The calibre of this monster hostile engine is 19 1/4 inches and the barrel is 44 feet long. The greatest diameter of the gun is six and one-half feet, and the range of fire is about 12 miles. The projectile is four feet long, weighs 2,700 pounds, and is fired by a charge of powder weighing 70 pounds.

In the manufactures of Great Britain alone the power which steam exerts is estimated to be equal to the manual labor of 4,000,000 of men, or more than double the number of males supposed to inhabit the globe.

INVENTORS, TAKE NOTICE!

L. PETERSON. MODEL MAKER, 228 Market St., N. E. cor. Front (up stairs) San Francisco. Experimental machinery and all kinds of models. Tin and brasswork. All communications STRICTLY CONFIDENTIAL.

Assessment Notices.

FALL RIVER CONSOLIDATED GOLD QUARTZ MINING COMPANY. LOCATION OF principal place of business, San Francisco, Cal. Location of works, Plumas County, Cal.

Notice is hereby given, that at a meeting in the Board of Directors, held on the 3d day of February, 1893, an assessment (No. 10) of two cents (2) per share, was levied upon the capital stock of the corporation, payable immediately in U. S. Gold Coins, to the Secretary, at the office of the Company, 313-315 Front St., San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 23d day of March, 1893, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the 17th day of April, 1893, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors, ADOLPH LORSBACH, Secretary. Office, 313-315 Front St., San Francisco, Cal.

SUPERIOR MILL AND MINING COMPANY. LOCATION of principal place of business, San Francisco, Cal. Location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of February 1893, an assessment (No. 1) of five cents (5c) per share was levied upon the Capital Stock of the Corporation, payable immediately in U. S. Gold Coin, to the Secretary, at the office of the Company, Room 2, No. 323 Front St., San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 20th day of March, 1893, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 5th day of April, 1893, at 1 o'clock P. M., to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors, I. N. WITHROW, Secretary pro tem. Office, Room 2, No. 323 Front St., San Francisco, Cal.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CAJALCO, Dec. 13, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager

The Mining Bill.

Both branches of Congress have adopted the Conference Committee's report on the Caminetti bill and it has gone to the President for his signature. It is probable that by the time this copy of the PRESS is in the hands of its readers the bill will have become a law. The modifications to the penal clause, noted by us last week, were adopted, as they should have been in the first place. The penal

would have been almost prohibitory to the industry if the Miners' Association had not blocked some little games toward the end of the proceedings in Congress.

The Bond Not Sufficient.

On another page is given the text of the decision of the Supreme Court with regard to the sufficiency of the bond filed in the suit of M. W. Fox vs. the Hale & Norcross

judgment of the Superior Court. The "mill-ring" people must have found out by this time that the Mining Stock Association means business, as it is persistent in its litigation and meets every move of those who have made money illegitimately out of the mines. The decision is another victory for the Association.

WATER-WHEEL AND AIR COMPRESSOR.—The adaptation of the Pelton water-wheel directly to the main shaft

INGERSOLL-SERGEANT DUPLEX GEARED AIR COMPRESSOR DRIVEN BY PELTON WATER-WHEEL ON MAIN SHAFT.

clause is restricted to apply only to such mines as may injure navigable streams. This, in truth, is all the Government has any interest in. If no navigable streams were injured it would be none of the Government's business at all.

The Legislature adopted a resolution asking the President to sign the bill, and there was not a dissenting vote in the House, which is somewhat remarkable. It has been a long fight to get this bill through, and it is not by any means all the miners hoped for. However, it legalizes the hydraulic-mining industry, under fixed conditions, and miners will have to deal with an intelligent, unbiased body of engineers, instead of a very different class of people. The bill is better than no legislation at all, but

Mining Co. As will be remembered, some time ago Judge Hebbard gave judgment against the defendants for over a million dollars. They gave notice of appeal and filed a bond with a guaranty company as security. This company was a new one and, it has been openly charged, was only formed to give this bond. The Supreme Court holds in brief that the Legislature never intended that a corporation with a paid-up capital of \$100,000 should be accepted as surety on a bond or undertaking in an amount many times in excess of its capital, and that the solvency and responsibility of the stockholders in the corporation could not affect the question. Under this decision the appeal to the Supreme Court does not stay the proceedings which have been or may be taken by the plaintiff to enforce the

of the Ingersoll air compressor is a feature of economy well adapted to the utilization of mountain streams where a height or head of from 50 to 1000 feet may be obtained. The lower heights have their power doubled by using the double nozzles and are now running at a mine in Peru, S. A. The engraving shows a sectionalized duplex Ingersoll plant, all made for mulehack transportation when so desired.

THE directors of the Denver Mining Exchange have fixed the list fee for 1893 at \$50 and the annual calling fee at \$25. A committee has been appointed to secure new properties on the Board. After March 15th no stock will be called that has not complied with the rules.

Comment.

It is stated that after the committee of managers and superintendents of Comstock mines has obtained the desired information concerning the cost of deep pumping operations, the miners' unions of Gold Hill and Virginia City will be asked to submit to a reduction in wages, which are now \$4 a day, and that the railroad, wood and water and other interests will be requested to make corresponding reductions, so as to offset the cost of pumping. It is said there is to be a proposed graduation of wages; that is, the men working very deep will be paid more than those working in the upper levels. The deep mining work in the heated portions of the mine is more arduous than that above. The miners should be reasonable in meeting this proposition, and not add labor troubles to the difficulties which already exist. It is not probable that any unreasonable demands will be made, but unless expenses are reduced all around, Comstock mining cannot prosper. The miners should wait for the proposition, whatever it may be, and give it careful consideration; but an absolute refusal in advance, of any reduction of wages, would, in all probability, bring the whole scheme of deep pumping to an end. If the miners leave there for most other camps, they will only get \$3 a day, so they can afford to treat with the managers unless some unreasonable demand is made.

The bond on the gold mines in Vanderhilt district, San Bernardino county, which W. S. Lyle and others secured for the honoza firm, has been taken up. The amount paid to the original owners is \$40,000. Messrs. Mackay, Flood and others, who now control the group, will expend about \$100,000 in developing the properties. Mr. Mackay himself, while on the coast, will visit these mines. If satisfied with them, it is said that the stocks of the companies to be incorporated will be listed on the stock boards in this city. This will be the first time the Nevada silver-mining millionaires have turned their attention to California gold mines, and it is characteristic of them that they should begin in the greatest silver-producing county of the State. They also take up an entirely new district in which to begin their operations. It is to be hoped that they have good properties, as there are plenty of good gold mines in California. Outside of those at Bolie, however, few of them have ever been listed on the boards for speculative purposes.

On another page is the first one of a series of articles by C. H. Aaron on silver-milling by amalgamation. Mr. Aaron's idea is to present some points not to be found in the standard works, but which are learned by experience.

As a general thing, millmen and "experts" keep such points to themselves as part of their professional equipment. These people are usually willing to absorb information, but seldom like to impart it. The younger men, who are more candid, have little to impart, while the older and more experienced keep what they know to themselves. Mr. Aaron is on exception to this. Not only has he written several books, but his contributions to the public press have been numerous. His writings are of a practical nature, and he possesses a faculty of making himself very clearly understood, so that any one may carry out easily what he describes. Those interested in the metallurgy of silver will find much of interest in the series of articles now running in the MINING AND SCIENTIFIC PRESS.

We were shown this week some pyritic ore from the Kennedy mine, of Amador county, in which the sulphurets were plainly gilded with a thin veneer of gold. The sulphurets look like those of ordinary nature, but the free-gold coating is apparent under a microscope. If stamped fine all this gold is lost, as it extremely fine and thin. If split up, the pyritic matter shows gold on the divisions in a thin film. It really looks as if the gold on the surface had been thinly gilded on. Fine stamping of such material cannot be done except with great loss. This peculiar ore is from the 1500-foot level of the Kennedy.

Mr. Kennedy's bill to turn the Mining Bureau over to the State University has been practically killed, one of the committees having reported against it. Senator Ford's bill, substituted for his original one, very clearly defines the duties of the State Minerologist and makes considerable changes in the present methods of conducting the bureau. On Thursday Mr. J. J. Crawford, of El Dorado county, was appointed State Minerologist by the Governor, to fill the place of Wm. Ireland Jr., whose term expires March 1st.

Both the hydraulic mining bills introduced by Senator Ford have passed the Senate but are still in the hands of the Assembly committee. One of these defines hydraulic mining and provides that it may be carried on under certain conditions. The other provides for the appointment of a State Debris Commissioner to cooperate and consult with the U. S. commission. It also appropriates \$250,000 for debris dams, if the Government appropriates a like amount. If Congress makes no appropriation the bill does not become operative. Senator Ford has shown commendable zeal and energy in getting these measures through the Senate. Mr. Thomas, of Nevada county, is anxious to push them in the Assembly, but Chairman Hamilton of the Mining Committee of the Assembly calls no meetings and pays little or no attention to his committee. This young gentleman is from Placer county, where the "miners' movement" started, and his constituents are all interested in these measures. He was given this chairmanship out of compliment to that county. There are many important measures waiting the action of this committee, but the other members are unable to get their chairman to show any activity.

Obtaining Title to Drift Mines.

The executive committee of the California Miners' Association appointed as a special committee Messrs. Ross E. Browne, John Hays Hammond and Chas. G. Yale to call to the attention of Senators and Representatives from the mining States certain objectionable features in the pending Stewart bill, especially those which threaten injury to the gravel-mining interests of California. One section of the bill provides that not more than 40 acres of placer ground shall be included in the same application for patent, and this provision will doubtless necessitate a development and \$500 work of improvement on each 40-acre lot.

The term "placer" includes all of our gravel mines—the deep hydraulic and drift mines, as well as the shallow placers. The shallow placers are readily accessible and easily worked, and for these reasons might well be restricted as provided in the bill; but the shallow placers in this State were the first to be discovered, are being limited in extent, are almost exhausted. The deep gravel deposits, on the other hand, are difficult to explore. When suitably situated and not capped with volcanic material, these deposits are worked by the hydraulic process, requiring expensive preparation—miles of ditching, fluming, piping, tunneling, etc.—necessitating, as a rule, the inclusion of many times 40 acres of ground in one property. When not suitably located for hydraulic mining or when covered with volcanic material, these deposits are worked by the drifting process and constitute the so-called "drift mines," which are now yielding a large part of our annual product of gold. It is necessary to include many times 40 acres in one drift-mining property, as will be shown.

There are many extensive areas of undeveloped hydraulic and drift mining ground in this State, constituting prac-

tically all of the gravel-mining ground of the State to-day. Most of our drift mining ground is covered with barren volcanic material to a depth of several hundred feet and a width of a mile or more. Only the bottom gravel pays for drifting, and this forms a narrow winding channel course buried and hidden under the large accumulation of barren material. Its position cannot be estimated closely enough to cover it with certainty with a 40-acre tract. As a rule, it must be drained and worked through long tunnels, say from 1000 to 5000 feet in length, which must be driven through hard bed-rock before reaching the deposit. The cost of such tunnels is so great that there must be included in one property a considerable length of channel, say a mile or more, in order to warrant the expense of opening. A claim, therefore, to have any value must contain many times 40 acres—say 300 or 400 acres, or more. It would be unreasonable to require that each 40-acre tract should be opened separately—there is not one case in 50 where the gravel is rich enough to justify such a thing. It follows that if the provision in the Stewart bill passes, the average drift miner will be virtually debarred from securing patent-title to his property.

Suppose his property contains 320 acres (a moderate-sized drift mine), and includes one mile length of channel. He drives a long bedrock tunnel, costing say between \$10,000 and \$100,000, and taps the pay-channel. He may then apply for patent for one 40-acre lot, covering say one-quarter mile of the channel. The customary delays of the land office are such that he will probably have worked out this length of channel before patent issues. He may then apply for the next 40-acre lot, and so on. He cannot complete his title until his ground is worked out and is no longer valuable for mineral. Meanwhile, if he desires to sell his property, he can give no guarantee of title.

It is not presumed that Senator Stewart intended to limit an application for patent to an area less than absolutely required to constitute a single workable property, but his bill certainly does this. This provision will not benefit the small miner in this State; on the contrary, it will be just as serious a blow to his interest as to the interest of the large corporation. This is a matter of vital importance to our gold-mining industry, and an effort should be made to have this provision (limiting an application for patent to placer ground to 40 acres) either eliminated or else so changed as to permit the inclusion, in one application for patent, of the entire area necessary to constitute one workable property, even though such area be as great as four or five hundred acres.

The Cost of Producing Silver.

Senator Stewart of Nevada, in his zeal to promote the interests of free silver coinage, has brought forward an argument which will scarcely encourage investment in silver-mining properties. He has gathered testimony to show that the cost of production of silver is in excess of its full coinage value. Of course the idea is to prove that silver is not overvalued in our coinage system as compared with the expense of obtaining it. The subject is brought up by a report of the Senate Committee on Mines and Mining, which is signed by Senators Stewart, Jones, Power, Felton and Call. The argument in the report is said to be very elaborate, and much testimony is brought to hear. Prof. James D. Hague says the cost of production on the Comstock per ounce of fine silver ranged from a minimum of 35 to 40 cents on the production of the Big Bonanza in its most prosperous period, and disregarding all prior and subsequent assessments to a maximum of \$2.10 on the production of nondividend-paying mines. Taking all their assessments into account, the average cost of all the silver produced on the whole lode from the beginning has been \$1.10 per ounce. The average cost of the silver product of the United States for 1891 was 85 cents per ounce, not allowing for assessments or other forms of new capital invested in the business.

Following are fair samples of the mass of testimony: Ex-Senator H. A. W. Tabor, Colorado: "If we take into account the large plants of machinery left on exhausted mines, and the many millions of dollars' worth of work without results, silver costs, as a whole, \$1.50 an ounce."

Ex-Senator N. P. Hill, Colorado: "My opinion is that, adding to the cost the losses of all the unprofitable enterprises in silver mining the total average cost for the past 10 years in producing silver in the United States would amount to more than \$1.29 per ounce."

W. C. Wynkoop, editor of the *Mining Industry and Tradesman*, Denver: "In 1890 I secured the reports of about 160 incorporated mines which produced silver during the preceding year. Taking the companies which did not make a profit in connection with those which did, the cost was about \$1.15 per ounce." For the whole United States Mr. Wynkoop believes the silver produced has cost on an average of \$2 an ounce.

W. F. Reinert, editor of the *State Mining Journal*, Denver: "I think it quite safe and very conservative to estimate the average cost of producing an ounce of silver in Colorado at from \$1.50 to \$1.75."

Louis A. Garnett, San Francisco, estimates the cost of

the silver produced on the Comstock at \$1.50 per ounce. Simeon Wenban of San Francisco, states that he can furnish bullion from one of his mines in Nevada at a cost of 63 cents per ounce, but thinks that all the silver produced in Nevada has averaged not less than \$1.30. William H. Watson and L. A. Raymond, San Francisco: "We can safely say in our experience that every dollar of silver we obtained cost us at least \$2." William E. Sharon, James H. Kinkead, D. B. Lyman, A. J. McDonnell, E. Boyle and C. C. Thomas, the leading mining superintendents on the Comstock: "The cost of producing an ounce of silver on the Comstock to-day is \$1.37." R. K. Colcord, Governor of Nevada, puts the cost of all the silver produced in that State at over \$1.50 per ounce. Surveyor-General J. E. Jones, Nevada, estimates it at from \$1.50 to \$2.

The report states that 99 per cent of the supposed discoveries and locations of mining claims on which money and labor have been expended have produced nothing and are failures. All this appears to be charged up to the productive mines, as regards the value of their output. Why, is not quite clear, except that prospecting is necessary to find new mines. Perhaps if expert judgment were taken, so much money would not be spent on what turn out failures.

At all events, while Senator Stewart's argument may have some effect on free coinage, it will do no good to the silver-mining industry. People will not care to invest in an industry of which 99 per cent of the operations are proven failures; and if a man has a rich producing mine, the failure of a dozen or so near by is not apt to enhance the value of his product. We cannot tell the reason for the failure of many mines to pay dividends regularly, but in the case of the Comstock there are reasons apparent to people here, outside of the ore in the mines themselves. Mismanagement and dishonesty have been factors of the greatest importance. Millions have been stolen from the shareholders which were rightly theirs. Great fortunes have been founded by people managing these properties, while the properties themselves have paid no dividends.

Mr. Wenban, quoted above as getting his silver at 63 cents an ounce, is the greatest individual silver-producer in the United States. He has made a great fortune out of legitimate silver mining, without the speculative feature. He has looked after the mines himself, as men would any ordinary business. He confesses that other mining operations have not been profitable, but gives no reason. Of course, there are many failures in this business, but we do not believe they amount to 99 per cent of the whole as stated. The report of this committee will be held up for years as one to discourage mining investments, though many of the statements are untenable. Among other things, it includes gold mining as also unprofitable. California alone has produced \$1,270,000,000 in gold, and it is absurd to say it cost that. The rich placers here and there in Montana in the early days would strike an immense balance of profit alone for the gold-mining industry. There is never any discount on gold, as it is the basis of all values.

The Robinson Riffle.

At his cyanide process plant in Shasta county, Mr. A. B. Paul is using the Robinson riffle which he has briefly referred to in some of his articles in the PRESS. Inquiry has been made as to the construction of this riffle, and we have made a little sketch of it which is given herewith.

The Robinson riffle is made of any width—according to quantity of water and material to flow through. For ten stamps it should be about 12 inches wide. To make it take 1x12" boards and cut them off in two-foot lengths for making the bottom A. Then take some 2x4" and cut 12-inch pieces off. Nail the 1x12 two feet long to the 2x4 pieces at say B, all for desired length. Being thus put together, nail all the pieces together at C, and put eight-inch sides to the whole of 1x8" boards. Give it a grade of from 15 inches to 18 inches to 12 feet in length. The grade depends on the material to be washed. The operation of the riffles makes an agitation on wheels at the points D, as water and pulp flow over the points B. Mr. Paul says this is a very cheap, simple and efficient concentrator of gold and sulphurets. Any one using it will soon find grade, etc.

A LIEN of \$3000, held by O. Lonkey against the Keyes mine in Seven-mile canyon, has been foreclosed by order of the District Court. There are a number of labor liens also filed on the property, the control of which is held in San Francisco.

THE Queen of the Hills mine, at Neihart, has shut down because the miners refused to work for \$2.75 a day, which was all the company said it could afford to pay.

The Comstock Tunnel Company's Affairs.

The case of Frank T. Symmes and others against the Union Trust Company of New York and others is being tried at Carson, Nev., before Judge Thomas P. Hawley of the United States Circuit Court. The outcome of this suit will interest a great many people on this coast, especially those connected with Comstock mining. The facts of the case are, briefly, that McCalmont Brothers & Company of London loaned the Sutro Tunnel Company in 1877 about half a million dollars, the interest of which run up a debt against the company of about one and a half millions in ten years, which was secured by a mortgage on the property, the terms of which mortgage permitted the mortgagees to foreclose for non-payment of interest. Default in payment of interest having been made in 1881, the mortgagees proceeded to foreclose in 1886, and were to have foreclosed on the 1st of January, 1889. A number of shareholders of the company finally interested Theodore Sutro to save the property from foreclosure, and Sutro set to work to raise the money to pay off the mortgage. First he managed to get a large reduction of interest on the ground that the McCalmonts had got control of the Board of Trustees and got unconscionable bargains in their favor against the stockholders of the company in the way of large interest and compound interest, until the mortgagees agreed to take about \$800,000 for their mortgage on January 1, 1888. If the money was not raised by that time they would insist on their entire claim, and would become entitled to the entire claim by reason of the agreement to raise the money and pay off the mortgage. Theodore Sutro labored indefatigably, but failed to raise the money in time. He nevertheless, knowing the McCalmonts to be very old men and exceedingly anxious to settle up the matter, still worked on to raise the money, but one plan after another failed, until he finally interested the Union Trust Company of New York to advance the money, which the company did, and became the owners of the McCalmont mortgage. The company also became the trustees of a syndicate and assenting stockholders of the Sutro Tunnel Company, by paying to the McCalmonts \$800,000, which sum had been subscribed by assenting stockholders to a new plan of reorganization.

Advertisements were then inserted in the leading papers in the United States and Europe, calling upon the stockholders to come in under the plan of reorganization and protect their interests by subscribing, and detailing the fact that there was no reasonable prospect that the foreclosure and sale of the property could be averted unless all the shareholders came in as subscribers to the bonds. On the first of October, 1888, the Union Trust Company obtained a decree of foreclosure, and the reorganization committee of the Sutro Tunnel Company proceeded to again advertise in Europe and in the United States, and addressing circulars to all the shareholders, giving them a final opportunity to come in and subscribe to the bonds and save their property and stock.

On the 14th of January, 1889, the property of the Sutro Tunnel Company, except a few blocks of land in the town of Sutro, was sold to the Union Trust Company under the decree of foreclosure and order of sale, for the sum of \$1,325,000. The Sutro Tunnel Company allowed the time of redemption to expire, and allowed the sale of the property to be confirmed, without attempting to redeem the property. The sale left an actual judgment in favor of the Union Trust Company against the Sutro Tunnel Company of \$110,000. The deed was made to the Union Trust Company as the appointee and trustee of the reorganization committee, and as a trustee for the syndicate, and for the stockholders who had subscribed for bonds under the new plan of reorganization.

The Comstock Tunnel Company was organized subsequently for the purpose of carrying into effect the terms of the syndicate agreement, and the reorganization plan, and as a result a large number of the shareholders of the Sutro Tunnel Company are shareholders of the Comstock Tunnel Company. Subsequently the Union Trust Company deeded the Sutro Tunnel property to the Comstock Tunnel Company. This latter company is wholly free from debt outside of its bonded indebtedness of \$2,139,000.

The complainants ask the court to set aside the decree of foreclosure and sale and the confirmation of the sale under the decree on the ground of fraud, and ask that the Union Trust Company of New York be declared the trustee of the Sutro Tunnel Company.

Mr. H. L. Gear, of this city, opened the argument and claimed constructive fraud and collusion on the part of Theodore Sutro with certain of the trustees of the Sutro Tunnel Company in permitting the sale of the property. The opening statement of Mr. Gear was such that counsel for respondents gave notice to the court that they would ask permission to reply to the closing argument of Mr. Houghton on all new points which Mr. Gear had failed to give notice of in his argument. On Tuesday,

therefore, Mr. Houghton reopened the case and went through it exhaustively, and claimed not only constructive but actual fraud had been committed in permitting the sale of the property. For three days Mr. Edmund Tausky spoke in behalf of the respondents, reviewing a great mass of testimony from the very inception of the Sutro Tunnel Company. He claims that the complainants have entered into a conspiracy to maintain the suit in bad faith, and that the bill of complaint does not contain any matter entitling complainants to any equitable relief. The trial is still going on.

Coast Industrial Notes.

This, as a yield for a single year will, no doubt, be quite astonishing to people who have looked upon Alaska as of little value to the United States.

A MINE of antimony has been recently found and located in the San Jacinto valley, near Perris, the ore of which is said to contain 66 per cent. of antimony.

THE Board of Trustees of Modesto have made the award of a contract for the erecting of new city water works to W. T. Garratt & Co. of San Francisco for \$51,200.

PRESIDENT HARRISON has issued a proclamation creating the Sierra Forest Reserve in the State of California. The reservation comprises approximately 6000 square miles in the counties of Merced, Fresno, Tulare and Kern.

THE Modesto Board of Trustees has awarded to Williams, Bessler & Co., of San Francisco, the contract to construct a sewerage system for that city. There were 22 bidders. The bonds voted for municipal improvements amount to \$85,000.

THE steam schooner Excelsior was launched from Mathews' shipyard at Eureka on Saturday last. The vessel is the largest steam schooner ever launched on the coast. She was built for the Excelsior Redwood Company of Eureka. She will be commanded by Captain Higgins. Mathews will immediately lay the keel of another vessel.

EASTERN CAPITALISTS, who have been negotiating for the purchase of water rights and right of way for a canal to irrigate 200,000 acres in the northern part of San Joaquin county, have telegraphed that their agent had started for Lodi to close the contract. The water will be taken from the Mokelumne river, near Valley Spring, and will be run on both sides of the river.

At the annual meeting of the stockholders of the Carrara marble quarry of Amador county the following named were elected directors for the ensuing year: President, P. Barbieri; vice-president, J. A. Baxter; treasurer, the Bank of California; secretary, C. Dondero, and G. B. Oenasco, M. J. Fontana, G. Bovo, A. Paltoughi, J. P. Freana, Ph. Giovannini, P. M. Ricci, A. Chichichizola, trustees.

UNDER the new State law the Supervisors of Mendocino county have awarded twenty-four road contracts for four years at the rate of \$24,000 per year. A street-car franchise has also been granted Attorney J. M. Mannon, president of the Ukiah City Council, who will lay a track on the county road from Ukiah three miles southeast to the State asylum. Under the franchise, which is to run fifty years, he may utilize horse or electric power.

THE prospects are very good for Santa Rosa securing one of the biggest shoe factories on the coast soon. A company is being organized with a capital stock of \$100,000, \$40,000 of which is to be paid up. The stock has been nearly all subscribed for, and it is expected that contracts will soon be closed. A large tannery will be operated in connection with the shoe factory and employment will be given to about 150 persons.

THE White Horse Valley Mill and Lumber Company, an association of landowners having about 20,000 acres in Modoc and Siskiyou counties, have elected the following officers: president, Emanuel Meyer; vice-president, Dr. T. N. Iglehart; treasurer, A. W. Myer; directors—P. Koppen, William F. Schulz, F. H. Merzback and Louis Cooks. Eugene W. Levy and James Hermann were respectively appointed secretary and attorney of the corporation.

WORK has already been begun on the electric road which will connect with the Valencia and Mission street and continue out to the boundary line along the Mission road. The rails have been laid from Thirtieth street out to a point opposite the House of Correction, and men are at work drilling the screw-holes preparatory to laying the rails. It is expected the ground will be broken for the first tie in a few days, and once started the poles and wires will be run up inside of ninety days.

THE Fruitvale Railroad running from the depot at Fruitvale, Alameda county, to the Hermitage, will be changed to an electric railway early in March. It is the intention of E. C. Sessions, the owner of the line, to still use the double double-deck cars, which will make it the only railway in the country where double-deck cars are run by electricity. The poles and trolley wires have already been placed in position, and this work of changing the line will be finished as soon as possible.

FROM careful observations of the Spring Valley Water Works it appears that the amount of rainfall up to the 12th inst., when the late storm was concluded, is fully double that to the same date in 1892. At the Pilarcitos reservoir, 44.23 inches has fallen, against 29.93 for 1892. At San Andreas 35.18 inches fell this year, against 18.94 last. At Crystal Springs 32.74 has fallen, against 15.18 last year, and in San Francisco the figures are 22.78 and 12.88 respectively. The total amount of water collected in the different reservoirs during the last storm, which extended from January 25 until February 12, was 2,777,000,000 gallons, or enough to supply the city for 150 days. The total amount of water in the reservoirs on the 12th inst. aggregated the vast quantity of 21,500,000,000 gallons, or enough to supply the city with 20,000,000 gallons per day for over three years.

The Kootenai Country.

David P. Kane, who, with his brother, George T. Kane, owns the townsite of Kaslo City, B. C., and also some of the richest mines in the Kootenai district, was at the Portland the other day, says the *Portland Oregonian*. When questioned in regard to the already famous Kootenai mining district, Mr. Kane said:

"That Kaslo, Slocan or Kootenai district is situated on Kootenai lake, about 150 miles north of Spokane, and contains the richest and most extensive bodies of silver ore ever discovered on the continent. The ore, none of which averages less than 150 ounces to the ton, and contains from 60 to 80 per cent of lead, is all high grade and embraces almost every combination of silver ores known. Of these ores known as 'gray copper' and 'antimony of silver' are the richest. It is not uncommon for specimens to assay as high as 5000 to 6000 ounces, and I have in my possession a specimen that assays 10,000 ounces. Two years ago there were not 50 people in the entire district, and now there are more than 30,000. The richest ledges were discovered about a year ago, and it is since that time that the greater part of the people has come in. Kaslo City is the natural center of the district. Two years ago my brother and I preempted the townsite, paying \$2.50 an acre for the land, and we did not commence selling town lots until about a year ago. At that time heavy timber covered the spot where to-day stands a thriving town of 1500 inhabitants, with business houses and residences that would do credit to Portland. On the principal streets property sells at the rate of \$80 per front foot. All of the finest mines are within a radius of 10 miles of this little town, and even the most remote finds are within a radius of 20 miles. A wagon road 30 miles in length, and costing \$37,000, has just been completed from Kaslo into the very heart of the district. All of the ore is brought in on this road and dumped on the docks; from that point it is shipped on steamers down Kootenai lake and river to the Great Northern railroad, where it is loaded on cars and carried to the smelters, either at Tacoma, Helena or Great Falls. The cost of the wagon road was defrayed by subscriptions, and the entire amount was raised in Kaslo in two days.

"The first shipment of ore, which was made not long ago, consisted of 10 tons, or half a carload. The ore was taken from the Dardanelles mine, and Mr. McLain, the owner, in order to convince the people of the district that the ore had netted him that amount, secured payment for the ore in fresh, crisp bills and placed them on exhibition in a prominent place in Kaslo. In the entire district there are now about 1000 locations, of which 600 are now paying mines. There are about 250 men employed in the mines themselves and the daily pay roll is more than \$600. Over 600 horses are at present employed in hauling ore on the great road, and the ore is being dumped on the docks at the rate of 50 tons per day. Just now the greater part of it goes to Tacoma, but an 80-ton smelter is being built on the lake, about 10 miles below Kaslo, which will be completed next summer, and it is probable that others will be built before long, so that in the future the ore will be reduced at home. A sampling works will be built at Kaslo this spring, so the buyers can purchase ore on the spot. A peculiar feature of the district is the fact that the ores crop out on the surface and require very little development. The pure galena is found in solid bodies and does not require concentration, as in other well-known districts. One of the mines already has a tramway, and another has just put in a fine diamond drill. In other mines these things have only come after the mines have been in operation for years and thousands of dollars have been spent in development.

"A singularly interesting feature of the population is the fact that the district is altogether American. Wherever the English flag is seen the stars and stripes are close beside it, and the Fourth of July is celebrated as it would be in the most patriotic American city. With one exception the capital invested is all American."

Growth of the U. S. Patent System.

The last report of the United States Commissioner of Patents contains several graphic exhibits of the growth in numbers of patents issued to citizens of the United States in the century ending 1890, and a study of these diagrams leads to some interesting deductions. The first law controlling the issue of patents in the United States was passed by Congress in 1790; though at that time about 1,700 patents or caveats had already been granted under previous crude enactments by local or state authority.

The development of the inventive faculties of Americans, says *Engineering News*, seems to have been very slow in the earlier years of our national existence, if the issue of patents is to be taken as a basis of estimate. With the population increasing in a steady but rapid upward curve, the issue of patents, as recorded on the chart, shows a very slow growth until after the middle of the present century was passed. The passage of the new patent laws of 1836 and 1870 showed a depressing rather than an encouraging effect upon the efforts of inventors.

The year of 1852 is the first point of marked departure in this respect, and the rate of issue increased from 1,020 patents issued in that year to 4819 issues in 1860. The effect of the Civil War was at first to decrease the number of applications, but the urgent call for new devices of all kinds, brought out by the war itself, soon overcame this slight depression, as is shown by the fact that in the interval 1862-67, through which period the war may be said to have still influenced inventors, the issues rose in numbers from 3521 to 13,025.

After 1867 the rate of yearly growth was steady and rapid, with some falling off in 1871, 1872 and 1879. In the year 1891 there were 40,552 applications; 2408 caveats were filed and 23,244 patents were issued.

The next chart shows the number of patents issued to individual States in the period 1790-1890, and per 1000 of State population annually. Up to about 1850 this ratio per 1000 was low, and in this respect the several groups of States did not differ widely, the highest ratio being less

than one per 1000. But the rapid increase in manufactures and the founding of great industries in the Eastern, Middle and Western States after that date caused a very marked growth in the ratio of patents granted, as contrasted with the agricultural States of the South and West. The wits of inventors were sharpened by the demands of surrounding conditions in the industrial communities; and Connecticut, famed for the introduction of basswood hams and wooden nutmegs in our earlier annals, maintains her supremacy for inventive genius throughout the century, with the highest ratio given, that of 13.1 patents yearly for 1000 of population.

As to the South, the list of patents granted annually shows that conditions are now rapidly changing, and the marked development of Southern industries indicates a corresponding encouragement to inventors. Alabama, for example, took out 103 patents in 1890, as contrasted with 62 in 1880 and 36 in 1870. Georgia, Louisiana and South and North Carolina show a similar late increase in issues, while Mississippi, Florida and Arkansas remain at about the same low ratio for years. Taken as States, regardless of population, New York comes first, with 101,989 patents granted in the period 1790-1890; Pennsylvania comes next, with 51,140; then Massachusetts, with 48,992; Ohio, 34,606; Illinois, 33,642, and Connecticut with 21,810 patents.

But the benefits of the patent system are by no means confined to the manufacturing industries. As the Commissioner of Patents points out in his report, it was the invention of the schoolmaster Whitney, in his improvement of the cotton gin, that made possible the marvelous cotton culture of the South; and the settlement, cultivation and growth of the Great West are due to patented improvements in agriculture and in transportation. Under previously existing conditions it would have required the labor of about 24,000,000 men and boys to plant, till and harvest the American corn crop of 1889, a laboring force considerably outnumbering the entire population of the United States in 1850.

Use of Nitro-Glycerine Powder.

After the accident that occurred to Charley Lane, about a month ago, the *Eureka Sentinel* wrote to the California Powder Works for their views in regard to the explosion, and elicited the following reply:

"The probable cause of the explosion you refer to was that when the cans were used for thawing dynamite a portion of the nitro-glycerine leaked out of the cartridges and settled at the bottom of the can, there forming a coating. The cans being afterward placed on a forge fire, were of course subjected to considerable heat, resulting in a decomposition of the nitro-glycerine coating mentioned. The water in the cans, acting as a sort of tamping, prevented the escape of the gases, set free by this decomposition, and helped cause the explosion."

The following instructions will apply to all explosive powder made from nitro-glycerine mixtures:

Hercules powder will freeze at 42 degrees Fahrenheit. It must be thawed out before using when frozen, not by roasting it before a hot fire, nor in any vessel over hot iron plates, nor by leaning it up against hot brick-work, steam boilers or near the fire in the blacksmith forge; nor by putting it into the oven or in hot water to thaw. If you thaw it by putting it into hot water, a drop of nitro-glycerine may escape from the cartridge and settle to the bottom; the next time another drop, and so on. By and by you want the vessel to heat some water in; you put it over a hot fire and then wonder how a can of water can possibly explode. When frozen, the best way to thaw the powder is to place sufficient cartridges for the day on a shelf in the top of a warm room; the next is to put the cartridges in a tin or copper can, and set that inside of another vessel containing boiling hot water, place a cover over the whole, and the powder is soon thawed. It should not be heated hotter than 212 degrees Fahrenheit, for soon after that it throws off noxious fumes by decomposition. It should be stored in a dry, cool and well-ventilated warehouse. When so stored, it will remain in good condition in any climate indefinitely.

When set on fire in any ordinary way, it burns away by slow combustion, which produces different and more noxious gases than when explosion ensues.

To insure a perfect explosion, primers must be used so that the exploding cap may be properly adjusted.

Hercules powder will explode by being exposed to a gradual heat of 380 degrees Fahrenheit; by being set on fire where it is closely confined in some strong casket that would not let the gases escape, and by explosion in it or into it of any powerful fulminate like the regular exploding cap or charge of gunpowder, gun cotton, nitro-glycerine or other powerful explosive.

In loading a hole, when the fire from a safety fuse reaches the copper cap it explodes violently, and the explosion of the cap explodes the powder by heat and concussion combined.

It is not required that the hole be over two-thirds the diameter required for black powder.

The powder must be packed close in the bottom of the hole, using a wood rammer. Hard wood is the best. If the hole is tamped with water, it is best to use cartridges that are of the right size for the holes and pack them down tightly. If the primer is to be used in water tamping, care must be taken before inserting the cap end of the fuse into the powder, to make it water-tight at the juncture of the cap with the fuse, with white lead, grease, tar or otherwise. In all cases, if the fuse and cap are in good condition, by pressing the paper of the primer close around the fuse at the end where the cap is fitted and tying it with a string, an explosion is insured after firing. After loading the hole, fill in with an inch or two of tamping of sand or clay carefully, so as not to displace the cap and primer, then with your hard-wood rammer pack as solid as you please, ramming in with your hand, not with a sledge.

Be sure that your fuse and cap are both dry and in good order, always using the best qualities of each, so that

no chances will be taken on having to dig out a hole on account of a misfire.

By observing these instructions, any powder that is made with a nitro-glycerine mixture may be used with safety.

Numbering of Iron.

The present mode of selling pig iron is by the appearance of the fracture of pig metal when broken, and the producing districts have different classifications for their metal. Some of these districts have three or four grades only, while others have as many as eight or ten, and we have the card of a charcoal iron company that designates 14 grades. This multiplicity of grades and the variations of the grading in different sections of the country will always be confusing, and must soon lead to the sale and purchase of pig iron by analysis. For all practical purposes we can resolve the numerous classifications to about the following grades:

Anthracite and Coke.—Nos. 1, 2 and 3 Foundry; Grey Forge; Mottled and White.

Charcoal.—Nos. 1, 2, 3 and 5 Foundry; and Nos. 1, 2, 3, 4, 5, 6 and 7 Carwheel.

Besides these, we have in the South the soft and silvery irons, and in Ohio the silicized irons containing from four to ten per cent of silicon, both used to soften other irons and make them run fluid. In addition, we have the low phosphorus and sulphur irons used in the open hearth and Bessemer process for making steel and the low silicon and high phosphorus irons used in the basic process.

The carbon in pig iron is what enables the eye to distinguish the different grades, the softest, grayest iron having almost all the carbon in the graphite or uncombined state, while the hard and white irons have it nearly or wholly combined.

Anthracite and Coke Irons.—No. 1 Foundry is the darkest of the numbers as well as the softest, as it contains the most graphitic carbon. It is used exclusively in the foundry. In appearance the fracture is dark in color, rough, open grain; tensile strength and elastic limit low; turns soft and tough.

No. 2 Foundry is more generally used in the foundry than any other grade. The grain is not so open and large as No. 1 Foundry, but the iron is harder and stronger, although less tough and brittle. These two grades, especially No. 1 Foundry, become very liquid when melted, and will run into castings of the frailest and finest structure. The high numbers do not become so liquid when melted as Nos. 1 and 2. Graphitic carbon and silicon are both less in No. 2 than in No. 1.

No. 3 Foundry is used for both mill and foundry purposes. It is much stronger than Nos. 1 and 2, the grain being closer and more compact. It turns hard, is less tough and more brittle than No. 2. The strength for tension seems to reach its limit in this grade. It is less liquid than Nos. 1 and 2, and is therefore better adapted to heavy castings. The percentages of graphitic carbon and silicon are smaller and combined carbon larger than in No. 2.

Grey Forge iron is midway between No. 3 Foundry and Mottled, and is used principally in rolling mills. It turns hard and is weaker than No. 3, color light and verging into a white background; grain very close. Graphitic carbon and silicon in smaller proportion than in No. 3, and combined carbon in larger.

Mottled.—Except in the case of heavy castings requiring great strength and closeness of grain, where it is mixed with other irons, mottled iron is used exclusively for puddling purposes. Turns with great difficulty, less tough and more brittle than Grey Forge. Graphitic carbon and silicon lower than in Grey Forge and combined carbon higher.

White.—It is only when a furnace is working badly that this grade is produced. It has a smooth, white fracture, no grain and is used exclusively in a rolling mill; tensile strength and elastic limit very low; too hard to turn or drill, as the carbon in this grade is about all in the combined state.

No. 1 Soft, in grain is similar to 1 and 2 Foundry, lighter in color, quite soft and fluid with fair strength.

No. 2 Soft, runs between a 2 and 3 Foundry, except that it is light in color and is higher in both graphitic carbon and silicon. These irons, together with silvery irons, which are light in color and high in graphitic carbon and silicon, are used, as the name would indicate, for mixing with stronger and closer grained iron to make them soft and run fluid.

Charcoal Irons.—Foundry Irons made from charcoal are considerably stronger, and, because of the fuel, are much freer from impurities than irons made from coke and coal. The grain of charcoal irons of the same numbers as coke runs closer. They are used in foundries where great strength is required in castings.

Car Wheel Irons.—No. 1 is the softest grade, of which very little is used. It will not chill, and is used for ordinary castings.

No. 2 is produced in considerable quantities. It is closer to grain, is generally free from chill, is used for making malleable castings from furnaces and in remelting old wheels for a softener.

No. 3 is a harder iron and chills from one-quarter to three-quarters of an inch; is much used with softer irons in manufacturing car wheels.

No. 4 is still harder iron and will chill from three-quarters to one and one-quarter inches. This grade is used almost entirely for car wheel purposes.

No. 5 is about half white in the pig, and will chill from one and one-quarter to one and three-quarters inches.

Nos. 6 and 7 are white iron.

Nos. 5, 6 and 7 are mixed with softer irons in car wheel mixtures, and are also used in making chilled rolls.

There does not seem to be any standard governing furnaces, so far as the analysis of the different grades are concerned. This is accounted for by the variations of the constituents in iron ores as well as the character of the fuel used, which make it impossible to establish an analysis that would be accepted by all furnaces as a standard.—Chas. W. Sisson's A B C of Iron.

Mineral Wealth of Eastern Oregon.

TRACY, OREGON, Feb. 4, 1893.

TO THE EDITOR:—Thinking that our old California and Nevada friends are not aware of the mineral wealth that lies in eastern Oregon we will endeavor to give a brief but positive statement concerning it.

At the present writing we are situated on the Elk Horn mountain, in Baker county, about 15 miles from Baker City. On this mountain there are two dividend-paying mines known as the Baisly-Elkhorn mine and the Robbins-Elkhorn mine. The first-named has two of the Bryan mills on the ground and in active operation. They turn out from 150 to 200 tons per month of concentrates and from \$5,000 to \$7,000 per month of the yellow metal. The entire force of men required to work the mills and mine will not exceed 35, not including the wood-choppers.

The ledge runs northeast and southwest and has two permanent walls. There are three pay chutes that are developed in a distance of 300 feet along the ledge at a depth of 300 feet. These chutes start at the surface on the ridge and appear to be all in one and about 180 feet in length, but at the 100-foot level there seems to be a break in the ledge and the ore chutes split into three, varying from 100 to 40 feet in length. At the 200-foot level all the chutes are perfect and the walls smooth, and stand about 80 degrees. At the 300-foot level the ore chutes still hold their length, but increase in width, ranging from four to 16 feet. The ore is an iron sulphuret ore, but it contains no lead. This mine has been worked only a few years and has plenty of ore in sight already opened to run the mills for at least one year. It has been worked from the grass roots down on a paying basis and has made its owners wealthy, they being mostly poor men starting in.

The Robbins-Elkhorn is the south extension and has large bodies of ore. The walls are not so perfect owing to the fact that the development work is in a canyon and the works are not deep enough to avoid the breaks of the canyon. The ore is the same class as the Baisly, but apparently of a higher grade. This mine also has a mill about three miles down the canyon, but the deep snows in winter make it impossible to run during the winter months.

About a half-mile up the mountain lie the Hurdy Gurdy, Grand View, Denny and the Elkhorn Gold Mountain groups. These ledges parallel with the first-named ledges. The Hurdy Gurdy company put up a two stamp mill last fall and gave their claim a fair test, but owing to the lateness of the season they shut down for the winter. During the winter they have let a contract for a 400-foot tunnel that will tap the vein some 250 or 300 feet deep, and they propose to start up for permanent work at an early date in the spring.

THE GRAND VIEW.—The Grand View lies north of the Hurdy Gurdy. One of the ledges of this group has been sampled for a distance of 300 feet on the surface and gave an average of \$157 per ton. This company also will start a tunnel in the spring that will tap the vein 300 feet deep.

DENNY GROUP.—Mr. L. W. Nelson, one of the owners of the Denny group, also president of the Baisly-Elkhorn Mining Company, has already in operation a tunnel that will bring to view this group of mines. We are informed that the present owners paid \$10,000 for the Denny group. This group lies south and parallel with the other two mentioned groups.

The Elkhorn Gold Mining Company will continue their development work commenced last fall as early in the spring as possible. This company are sanguine of their prospect and expect to erect a Crawford mill early in the summer.

Mr. S. J. Fose, president and manager of the Grand View group, informs us that the Elkhorn mountain has not been thoroughly prospected yet, and that the coming season will only be the first step toward prospecting this mountain.

The advantages for wood and water cannot be excelled in any country. The Elk Horn mining district is among the richest districts in Oregon, and if we are not badly fooled, it will class with the rich districts of the Pacific coast ere another summer passes. We have not mentioned all the prospects in this district that will be worked during the coming summer. There are some rich prospects and some that can be classed as mines on the north slope of the mountain. The Robinson mine is a dividend mine and has new mills which are running steadily. This mine is only two and one-half miles from the Baisly Elkhorn mine, but is on the north slope of the mountain. We have only mentioned a part of the mines on the south slope. The ores in this district range from \$5 to \$500 per ton in gold.

There are three streams of water that join about a mile below the B. E. mill, one of which passes by the mill. The mountain is well supplied with timber and water. The only drawback to the camp is the lack of proper reduction works.

The Elkhorn mountain can be tapped by a tunnel a mile and one-half long that will tap all of the above mines mentioned on the south slope, a depth ranging from 2000 to 3000 feet deep. There is a good location for a tunnel site about a mile below the B. E. and R. E. mines that will tap these two mines, that are now paying dividends under the process which they are worked, something near 2000 feet deep. The site for reduction works and advantage of timber and water makes it a good investment to the company that takes the project in hand.

Those of you that are versed in the famous Sutro tunnel and the royalty that it has paid to the owners, would think strange for us to say that a tunnel in the Elkhorn mountain would be a better paying proposition than the Sutro tunnel, according to the capital invested. This project would not cost one-third what the Sutro did, and as we have sampled and prospected both Six Mile Canyon and Elkhorn mountain, we would willingly, and what we believe to be truthfully, say that there would be more in one-third of the ore that passes through this tunnel, than the entire amount that passes through the Sutro per year. There is no mining

capital in Oregon like the good old States of Nevada and California, but according to the amount of mining capital invested in Oregon, we will place her with any State as regards a paying proposition. True there has been lots of money spent in eastern Oregon in the way of mills and "wild-cat" mining schemes, but bring up all monies spent in mining projects, and Eastern Oregon will pay as many mills on the dollar, for capital invested, as any other State. And we can furnish as big mines in eastern Oregon as any State, according to development work. Lest some may think we are dwelling too much on one district, we will mention what you may look for in our next.

If all is favorable, in our next article we will endeavor to give a brief description of the White Swan and Vistin districts, located about 12 miles east of Baker City, while this camp is 15 miles west, and in fact we shall continue until all our districts are made known to the readers of the PRESS.

We have no religious, political, mining or social axe to grind in this or any other community, but we intend to communicate to the hungry miner and world the actual mineral wealth as we actually see it in eastern Oregon.

D. E. CUMMINS.

Some Points in Silver-Milling by Amalgamation.

TO THE EDITOR:—The present low and prospective lower price of silver makes a close study of the methods of its extraction more than ever necessary, and I offer a few points from my experience with some, though faint, hope that others may do likewise, which would surely inure to the benefit of the industry.

Silver-milling differs from gold-milling in that it is more of a chemical and less a merely mechanical operation, in so far as amalgamation is concerned. The gold which may be collected by means of quicksilver is already in the metallic state, and, while chemical considerations are not foreign to the subject, yet the main problem is the mechanical one of forcing the gold to intimate contact with the mercury, after freeing it from its rocky envelope. Silver, in ores, is almost invariably in some form of chemical combination from which it must be released by chemical action before it can be united with mercury as an amalgam.

Silver exists in ores in many different combinations, and these compounds are often chemically combined or intimately mixed with base metal compounds, which complicate the process of extracting the precious metal.

An example of the mixture of a silver compound with a base metal compound is seen in some argentiferous galenas, which, when triturated with moist sodium disulphate (sodium hydrogen sulphate), yield hydrogen sulphide, lead sulphate, and silver sulphide, the latter not being acted on by the reagent; in jalpaite, on the other hand, it is probable that the silver and copper exist as a double sulphide.

Among the native compounds of silver, the chloride, bromide and iodide are perhaps the only ones which can be metallized by simple contact with iron in the presence of water, and even with these the effect is promoted by an addition of salt and the application of heat. According to some authorities, silver glance (silver sulphide) yields the metal under the electrochemical action of iron and quicksilver in presence of hot brine, but it does so better if bluestone is also added to form cupric chloride by the aid of the salt. Other compounds generally necessitate the use of bluestone and salt, and even native metallic silver is much more readily recovered with than without such aid.

The copper chlorides, cuprous and cupric, and salt, are the only "chemicals" that are of general practical utility in the amalgamation of silver, and, in order that they may be effective, the ore, in the state of fine powder, must be exposed to their action, in hot solution for a certain length of time, depending on the character of the ore and the degree of comminution. Whether or not some of the silver ores, under these conditions, yield silver chloride, which dissolves in the brine, is a disputed point which need not be discussed here; what we know is, that the silver compounds yield the silver in a free state on contact with a relatively positive metal, as zinc, iron, lead, copper, or even quicksilver alone, the latter being at once the most expensive and the slowest, and it is only used in that way, intentionally, in the patio process.

In order that the bluestone may be effective, either the ore must contain no substance, except the silver compounds, which can decompose cupric sulphate or chloride, or such substance must be saturated. This may be done by using a sufficiency of bluestone, or, in some cases, by the cheaper sulphate of iron, or by sulphuric acid, sulphurous acid, sodium disulphate, etc. Thus, if earthy carbonate, lead carbonate or manganese oxides cause the trouble, either of the above substances will answer, some bluestone being also added unless the ore contains copper oxide or carbonate, in which case bluestone may not be required; but if the difficulty is caused by zinc-blende, galena or other sulphurets having the property of decomposing the copper chlorides, it is doubtful if you will not have to use an abundance of bluestone or give up its use entirely. Some ores contain so much of such substances that it will not pay to saturate them; and if they cannot be worked satisfactorily without, the best thing to do is to roast them with an admixture of pyritous ore and salt. There is, however, one case among these in which it may be feasible to treat the ore in the raw state—that is, when the only injurious substance present is calcium carbonate (or, probably, other earthy carbonates). Sterry Huot states that cuprous chloride is not decomposed by carbonate of lime, and, if this is correct, cuprous chloride might be readily made and used in place of bluestone, salt being added to dissolve it.

But it is not alone the composition of the ore that must be considered in this connection. The iron of the amalgamating-pan is constantly destroying the copper chlorides by precipitating the copper, which goes into the amalgam, and produces ferrous chloride which is of little use in the operation; hence it is desirable to retard this action as

much as possible, which end is promoted by crushing the ore as finely as may be needful in the battery and working the pan with the muller raised just enough to avoid grinding. If this be done, the entire iron surface soon acquires a coating of amalgam of silver, copper and perhaps lead, which diminishes the chemical activity of the iron. On the other hand, if the muller is allowed to grind the ore, the surfaces of the shoes and dies are kept free. Nor is this all. The pulp is pervaded by particles of iron ground off from the shoes and dies, and all soluble salts of copper are quickly decomposed.

In working roasted (chloridized) ore, it is not usually necessary to use any chemicals; yet, if the ore contains copper or lead, it is best to grind only so much as may be necessary to crush any lumps which may have been formed in the furnace; thus equally good results can be obtained as by grinding, and the bullion will be of a better quality. In regard to using an alkali in the pan when working roasted ore containing copper or lead, with a view to making finer bullion, by precipitating those base metals as oxides, it must be done with caution; if enough of alkali be used to completely precipitate the copper and lead as oxides, and to keep them in that state notwithstanding the constant tendency of ferrous chloride, produced by the decomposition of silver chloride, to cause their resolution, fine bullion will certainly be got, but there will be a larger loss of silver in the tailings.

Possibly carbonate of lime may not have this effect; I suggest its trial. My practice is to keep adding a little alkali, but never enough to quite prevent the staining of a knife-blade by the hot pulp.

The foregoing explains why it is that a roasted ore which forms a pulp with alkaline reaction, though yielding fine bullion despite the presence of lead or copper in the ore, yet does not give so satisfactory results as an "acid roast." This forms the exception to the rule that roasted ore requires no chemicals in the pan, for, if it can be done with economy, it will be advantageous to add sulphate of iron, or acid to such a pulp. However, it generally requires too much to counteract the alkalinity, and all that may be used will be wasted unless that result be attained.

One reason why an alkaline pulp makes richer tailings is that, in roasted ore, a part of the silver is usually combined otherwise than as chloride and, although iron reduces the chloride to metal, in the presence of alkali, it does not reduce some of the other compounds under such conditions. Some of these compounds seem to be double or multiple sulphates. Another probable reason is that, in an alkaline pulp, the iron surfaces remain free from any coating of quicksilver or amalgam, a state of things which is very disadvantageous for the collection of the silver.

C. H. AARON.

The Occurrence of Diamonds.

SAN FRANCISCO, Feb. 18, 1893.

TO THE EDITOR:—That diamonds exist in the auriferous gravels of California has long been known, and quite a large number has been found in various localities along the gold-belt.

The exhibition of rough diamonds in the exhibit of the State Mining Bureau at the Mechanics' Fair just closed in San Francisco attracted a great deal of attention, and was the cause of much comment and inquiry, particularly among mining men.

It is with a view to presenting some of their most common physical characteristics and the conditions under which they occur that this article is written. It may be that miners whose field of operation is in the placer mining region may by closer observation be led to the discovery of more of these rare and valuable stones.

In the first place, a very common idea that "California diamond" is synonymous with rock crystal, which is a transparent variety of quartz, must be laid aside. A California diamond is as much a gem as those found in South Africa, India or Brazil. They are similar in chemical composition, hardness, and every other feature, and a clear or first-water diamond, free from flaw and of a given weight, is just as valuable as a similar stone from the great Kimberly field in South Africa.

In the tailings of mills crushing cemented auriferous gravel in California the fragments of diamonds have been found, which is a positive indication that these precious stones may be found in the old river channels as well as in the more recent superficial gravel deposits.

The diamond is usually found in the form of an octahedron. That is a crystal having eight faces. These faces are triangular and are arranged in the form of two pyramids placed base to base. It is an exceedingly hard mineral, in fact the hardest of all known substances. In the scale of hardness of minerals it stands at the top—No. 10. Quartz is No. 7 and scratches glass. Topaz is No. 8, cutting quartz without difficulty. Sapphire, or corundum (emery), is No. 9.

The diamond is also a very heavy stone, having a specific gravity of 3.525 as compared with quartz at 2.65. In color it has a wide range, having been found in all the colors of the spectrum. Ordinarily, however, it is white, yellow, brown, or colorless, and more rarely rose-red, red, blue and green.

About 95 per cent of the diamonds now mined are from the Kimberly fields in South Africa.

The hardness is the best test. If corundum will not scratch it, and if a diamond will not scratch the specimen, the probability is, that it is a diamond.

In the United States, diamonds are found in two widely-separated localities, viz., along the eastern base of the Alleghany range, from Virginia to Georgia, and, in the West along the western base of the Sierra Nevada, through northern California to Oregon.

In both cases the diamonds are found in gravel with loose earth, and are associated with garnets and iron sands and less common minerals, and more particularly with gold.

The diamonds are undoubtedly derived from the crystal-

line rocks of the mountains. A rock which appears to occur in several diamond-producing regions is called itacolumite. This is a sandstone which splits off in slabs like flagstones, and contains scales of mica. The peculiarity of this rock is, that it will bend somewhat before breaking, and, if the pressure is removed, will resume its former shape, being therefore elastic.

The most common rock in American localities, and also in Brazil and India, is granite. All authorities do not agree that the flexible sandstone is the true matrix of the diamond.

In South Africa, where the greater number of diamonds are found, and those of greatest value, the formation is shale, containing a considerable amount of carbon; in fact, so much that when ignited the shale will burn.

Through this deposit of carbonaceous shale has burst a mass of eruptive rock, known to geologists as "peridotite." It seems that the diamonds have formed from the carbon of the shale by the intense heat, and, doubtless, vapors and gases accompanying the eruption of this volcanic rock. Peridotite is the name of a division of rocks consisting largely of olivine.

Observe the black lava found on the deserts of Nevada and California and in some of it you will see small bottle-green crystals more or less transparent. The chances are, that should you see such a mineral, it would be olivine. When it occurs in large amount, excluding the feldspars, it is called peridotite.

Now, it would seem useless to search for diamonds unless the carbonaceous matter were also present in the vicinity. The method of prospecting is by sifting the loose debris caused by the decay and disintegration of these rocks, and panning down like washing for gold.

To the casual observer the diamond may look like an ordinary quartz pebble, excepting its crystalline form—the octahedron, or a modification of it. The edges are usually rounded somewhat, and occasionally the diamond will be found twinned, that is, one crystal growing into or penetrating another. It has a peculiar submetallic luster—adamantine. Some diamonds look as though they had been rubbed over with stove polish.

The peridotite is usually dark green or bluish, and often almost black, with a rough, hackley fracture—tough, but soft enough to be easily scratched with a knife.

The Hale & Norcross Decision.

The Supreme Court last week rejected the undertaking on appeal in the matter of the suit of W. M. Fox vs. the Hale & Norcross Silver Mining Company, Alvinza Hayward, the estate of W. S. Hobart, and others. It will be remembered that in this case Judge Hebbard gave judgment against defendants in an amount exceeding \$1,000,000. The undertaking on appeal was \$2,030,000. This was duly filed. The only surety was the Western Safety and Guarantee Company, with a capital stock of \$100,000. Fox excepted to the sufficiency of this undertaking and asked that the court proceed to enforce its judgment by the issuance of an execution, notwithstanding the undertaking filed on appeal by the defendants.

The defendants then applied to the Supreme Court for a writ of prohibition to restrain Judge Hebbard from issuing an execution pending the determination of the appeal. In its opinion the Supreme Court takes substantially the same ground taken by the plaintiff when he objected to the sufficiency of the undertaking. The Court says in effect that a corporation having a paid-up capital of only \$100,000 manifestly cannot pay a loss of \$2,000,000 any more than a natural person can. The application for a writ of prohibition was dismissed. It is understood that the defendants will at once ask the Supreme Court to grant them permission to file a new bond. The court says in part as follows:

"The single question submitted for decision was whether this corporation, with a paid-up capital of barely \$100,000, is sufficient as sole surety upon an undertaking to secure more than 20 times that sum. The proposition that it is in fact sufficient is on its face a palpable absurdity. A corporation which has only \$100,000 can no more pay a loss of \$2,000,000 than a natural person can.

"It is true that there is a personal liability on the part of the stockholders of a corporation for their proportion of its debts, and it is suggested that it was shown that some of the stockholders of this corporation were men of large means. But this fact does not help us to a construction of the law. Counsel for petitioners could not deny that the solvency and sufficiency of the stockholders of such corporations is a circumstance of which the law takes no account. If under the statute upon which they rely this undertaking is sufficient it would be equally so if its amount, instead of \$2,000,000, had been \$20,000,000, and if the stockholders, instead of being in some instances men of means, were every one of them notoriously insolvent."

The decision is written by Chief Justice Beatty and concurred in by Justices De Haven, Paterson, Harrison and Garoutte.

STEALERS OF PATENTS.—A business man in this city who is up to his ears in the work necessary to gather capital to float an enterprise, and at the same time to keep information of the nature of it away from busy rivals, found time last week to say: "Did you ever think that a patent does not patent in this country? Well, it's a fact. All that the Patent Office does is to give you a paper with some writing on it, but if another man steals your idea and goes to manufacturing your invention, the Patent Office will not lift a finger to protect you or to stand by its own decision. The fact that you've got a patent is a point in your favor, but you've got to hire lawyers and fight the thief in the courts, and if he can stand it to hire lawyers longer than you can that settles you, and you might as well make him a present of your invention. There are lots of men in the

country getting rich on the discoveries of other people. All they had to do was to take them, and fight the real discoverers into poverty. The Patent Office, to be respected and to be of any use, ought to have the power to cause the stealer of a patent to be sent to prison."—New York Sun.

The State's Work in Forestry.

In the various sentiments expressed in favor of the abolition of the commissions which were brought into existence about ten years ago, those favoring the lopping-off of the Forestry Commission have been most pointed and pronounced. In fact the commission suggested its own taking-off, and in the face of such a disposition to commit legal hari-kari, the Governor in his message could do nothing but yield a mournful assent, and proposed that the Fish Commission should fall heir to the remains. Thus the Forestry Commission came into the halls of the legislature with the death-damp on its brow—in most fit condition for burial, one would think. Though something has been done looking toward the obsequies, the funeral director has not yet been chosen and the corpse lies in state in Sacramento.

The forestry commission must unquestionably be pronounced a failure so far as any finished work in the advancement of forestry is concerned. It has been during recent years a most conspicuous example of appointive errors. The members of the board, though gentlemen of quality and eminence in legal and business lines, were apparently without the slightest convictions, knowledge or taste in forestry. Their appointees were in part like unto themselves and the man or two among them who did know trees and their uses was powerless to accomplish much because he found neither knowledge nor appreciation of the work among his patrons or associates. So far as we know the personnel of the State Board of Forestry was composed of men who could do anything and everything else in the line of public executive work better than they could conduct a forestry enterprise. In view of this fact it is perhaps natural that they should ask to be relieved. It is only too bad that they did not retire at the beginning and not fritter away a vast sum of money, waste years of valuable time and bring one of the most important lines of Government work into disrepute, making it to sink in the nostrils of the people so that the Governor could think of nothing else to do with it than to pass it along for the experts in stale fish to appropriately bury.

Now, though the forestry work of the State has fallen into such hard lines, we do not lack faith in State forestry. The work was well conceived. The first appointees on the board were, in part at least, men full of the importance of the work entrusted to them and full of knowledge as to the way in which it should be done. If such men had been kept in office, California would stand foremost among the States in measures for the conservation of forests and in the reforesting of waste or lumbered regions. There would also have been forestry stations, which would have yielded information to public and private tree-planters worth many times the cost of their maintenance. We admit it is disheartening, after seeing large amounts of public money frittered away, to think of maintaining such a State enterprise, and yet we are sure that, with the appointment of a proper board, vast benefits could be realized. The testimony of Mr. Abbot Kinney, a member of the first forestry board of California, recently given before a committee at Sacramento, is strictly true:

"The Board of Forestry did a good work in the past, and it can do so again. It's about the only State Board that ever secured over \$50,000 worth of property and turned it over to the State. This the Forestry Board did in securing the experiment stations at Chico, Hesperia, Santa Monica and other points. The early forestry boards helped the Government secure evidence against the big timber thieves and largely checked the wholesale depredations.

Just now, under the Paddock bill, there will be work for a State Forestry Board to carry out plans for preserving and protecting the various Sierra forest reservations. The Yosemite reserve is now protected simply by a policing system by soldiers. There should be arrangements for licensing the sheepmen to pasture their flocks at certain times in certain sections. The cattlemen are now favoring this idea and demanding that some adequate grazing system be adopted. Besides the great Yosemite forest reservation, there are now five other Government reservations for parks, including the Sequoia grant, San Bernardino and Trabuco. The San Bernardino embraces the forests on Mount San Bernardino and the water supply of Riverside and surrounding country. The Trabuco reserve is in the Santa Ana range, partly in Orange and partly in San Diego counties. The Government irrigation work, with the setting apart of reservoirs and the preservation of water-sheds, is also right in line with work which could be done by our Forestry Board if it could be kept entirely out of politics.

The fall of the Forestry Commission carries down with it all these measures and interests, so far as the State is concerned, unless this legislature make some provision for their continuance. The forestry stations will lapse into ruins. This property, given in good faith to the State by generous individuals, will fall ere long into the hands of some schemer, who may buy it, with other old junk, from the State Capital. This is certainly a painful and ignominious end for a great State undertaking. We think the legislature owes it to the people that some better solution of the question should be brought forward than has thus far appeared.

N. M. CHANCE in an article on the Anthracite coal industry, states that 55 per cent of the coal in beds is rendered unavailable, this great waste resulting from using the old method of working by parallel breasts, separated by regular pillars of coal. By adopting modifications in the long-wall system, or combined long-wall and relling systems, a much larger percentage of coal in the thicker seams could be recovered, but such systems would perhaps increase the cost per ton, and they require a large preliminary outlay in deadwork before mining on a large scale can be commenced.

Steel and Iron for Mine Timbering.

At a meeting of the Manchester Geological Society in the mining school, Wigan (reported in *Iron*), Mr. Isaiah Johnson, of the West Houghton Coal and Cannel Company, read a paper on "The Substitution of Steel or Iron for Timber in Mines." For more than 20 years, he said, it had fallen to his lot to have charge of underground workings, and during that time he had almost daily to supervise the setting and taking out of timber. While superintending those operations the thought had repeatedly occurred to his mind, could not something of a more durable character than timber be used, so as to do away with the necessity of having to retimber the main roads about every 12 months. After careful consideration, he resolved to try the use of iron props and steel girders, and his first attempt was in a main road ten feet wide. He secured his road for a distance of 300 yards with iron props and steel girders, and covered with $\frac{3}{4}$ -inch boilerplate, the girders being set about three feet apart. This was done six years ago, and he had not, as yet, had to take out or replace a single girder. They had now altogether 1400 yards of main roads secured with steel and iron, and about 1200 yards of that length was set in roads which would soon destroy the best-known timber for mining purposes, viz., larch, as even that class of timber would not last more than 12 months at the longest. During that time, even with the greatest possible care, there would very likely be breakdowns, and sometimes heavy falls, causing a stoppage of work and loss to both workmen and employers. In addition to that, in bad ground, there might be falls which would stop the work for two or three days, and this would, as they were all aware, cause considerable loss to all concerned.

The girders they were using for main roads were 10 feet long, 5 feet by 4 inches by $\frac{3}{4}$ inch, and the section of the props was 5 inches by 3 inches by $\frac{3}{4}$ inch. The cost of one girder, 10 feet long, and two steel props 6 feet long, and 30 square feet of $\frac{3}{4}$ -inch boilerplate, would be about 31s. per lineal or running yard. For securing the same area with timber, the cost would be from 10s. to 12s. per yard. Evidently the first cost of steel and iron would be nearly three times that of ordinary timber, but then the life of the former would be at least six times that of the latter, and would at the same time save the labor of refixing and the risk of falls, and consequent stoppages during working hours. He said at least six times the life of timber, because he had already proved it, and yet, so far as he could see and judge, it might last another six years, for, speaking generally, the road alluded to was as good as when first done; therefore, as time went on, the great cost of the first outlay was gradually and yearly being returned.

He, therefore, claimed for steel and iron the following advantages: That its life was at least six times that of timber; that there was, proportionately, less risk; there were no stoppages through falls; and that when a road was done with the materials could be again used, or even if they had to be sold they would at least take scrap price, whereas timber, when broken, would be worthless. Therefore, considering the cost of labor and the danger of taking out old timber and refixing new, which was very costly apart from risk, he was convinced that the use of steel and iron for securing main roads was preferable to timber.

In the discussion which followed, several members, including Mr. Burrows, Mr. MacGeever and Mr. Boole, generally expressed the opinion that, under certain conditions, iron and steel girders were very useful, but where the mine was easing down they were of the opinion that timber props were preferable; in fact it very much depended upon the conditions of the mine as to whether iron and steel girders were preferable to ordinary timber.

Mr. Henry Hall, Inspector of Mines, said he agreed very much with the conclusions arrived at by previous speakers; iron and steel girders were excellent where there was no moving weight in the roof, but where there was a moving weight they could get over the difficulty much better with timber. The best form in which he had seen these iron girders employed was upon masonry side-walls three feet thick. Where there was no great amount of moving weight they could get very satisfactory results; but so far as he had observed, the placing of iron or steel girders upon the top of timber props gave very unsatisfactory results. If they had a road which was specially difficult to manage, he thought they would have to fall back upon timber. The method of using these iron and steel girders might be considerably improved if it were made more constructive. In that neighborhood they dealt with the iron props and steel girders simply, but if they were more built together in some constructive form, it would be much better. On this question, he might remark, both with regard to wood and iron, that some of the difficulties arising might be avoided by constantly watching the ends of the baulks, so that requisite precautions might be taken whenever the crush came on. A good deal of timber might be saved if this point were more closely watched.

The chairman (Mr. W. Saint) said he had been watching the introduction of iron girders for some time past, and he had paid attention more particularly as to how they were affected under moving weights and side pressure, and the great difficulty there was in getting them out. These iron girders and props were far more dangerous to get out than ordinary timber, as they were liable to fly out when the weight was removed, and there was danger of catching the men.

THE CON. New York Mining Company has declared a dividend (No. 1) of ten cents per share, aggregating \$10,000, payable Feb. 15th. This is the first dividend declared by the company. There have been nine assessments levied, the last on Nov. 2, 1892, the total amount in assessments being \$130,000. After paying the dividend the company will have \$9100 left in the treasury.

Mechanical Progress.

Brush-Making Machines.

Brush-making is largely carried on by hand, mainly on account of the delicate manipulation required in some of the operations, and also perhaps because no mechanical genius has hitherto been found capable of coping fully with the difficulties involved. An innovation, however, has recently been made in this direction, by the introduction of two very ingenious machines into the brush manufacture by Messrs. G. B. Kent & Sons. These are a machine for ganging knots of bristles for brushes and brooms and a drill for making the holes in tooth-brush blanks, and which we recently saw in operation at Messrs. Kent's works at Victoria Park, London. Hitherto the process by bunching the bristles and drawing them into the holes has been performed by hand. The operator forms a loop in the wire, which is first passed through the hole in the brush-back, and then takes a bunch of bristles, which are placed in the loop, and, pulling the wire, draws the bunch into the hole, these operations being repeated until the brush-back is full. In this machine the bristles are contained in a hopper in which they rest horizontally at right angles on the top of a disc, which, by means of a treadle, is caused to partially rotate, first in one direction and then in the other. The disc has a notch formed in its periphery, and as the notch passes under the bristles some of them enter into the notch. Before the disc returns, a plate joined to the disc is moved, and closes the mouth of the notch, the disc then comes back and carries away the tuft of bristle retained in the notch to a position from which it can readily be taken by the fingers of the operative. The whole arrangement is that of a pecker or gripper, and the gripper can be regulated according to the quality of the material required to fill the hole. The operative passes the wire through the hole by means of a special needle fixed to a clamp, which she holds in her right hand, the loop being automatically formed. Into this loop she passes the tuft of bristles, pulls the wire, and thus draws the bristles into the hole, repeating the operation at each hole until they are all filled. The work is rapidly performed, and an expert can draw about 1800 knots or bunches per hour. The saving effected by the use of these machines is stated to be about 40 per cent., the output being about doubled. Although there is this gain to the manufacturer there is no loss to the operatives, who expressed their satisfaction with the machine.

The drilling machine to which we have referred is also an ingenious piece of mechanism. It is upon the multiple principle, the head of the brush being completely drilled at one thrust, the drills being carried in a fixed head and making 2500 revolutions per minute. The drills are arranged in the required form, and the tooth-brush blank is fixed in a traversing holder between a pair of centre jaws. The holder advances to the drills, and when the holes have been formed the holder retreats, the blank is taken out, and another blank put in its place for drilling. The rate of speed is about five backs per minute, or 300 per hour, which is a remarkable advance on manual labor. Both the machines are the patented inventions of Messrs Kent & Sons, and are manufactured at their works. The machines produce work similar in appearance and equal in quality to the best hand work.—Iron.

An Unusual Foundry Experience.

Having learned that in the foundry of the A. L. Sweet Iron Works, Medina, N. Y., an accident had occurred which seemed somewhat mysterious, we wrote the company for some information regarding it, our object being to give all possible publicity to the causes which may bring about injury to those employed in industrial works.

In reply, we have received from Mr. Albert L. Sweet, the proprietor of the works named, a very courteous letter, giving the desired information so far as possible, for which our readers, most of whom have more or less to do with foundries, will, of course, feel grateful to him. We shall hope some of our readers may be able to throw further light on the subject, and we invite brief communications with that object in view. The essential part of Mr. Sweet's letter is as follows:

We were melting a fifteen-ton heat in a newly-lined cupola, and soon after the blast went on a number of our men were affected by gas. Out of about fifty employed in the room, seventeen were so overcome that it required prompt medical aid to restore them. They seemed to become paralyzed to a certain extent, and unable to help themselves. Some of them seemed to suffer intense

agony, while others seemed more in a paralyzed condition. And from the statement of the doctors who handled the cases, it seemed to paralyze the lungs to such an extent that it was necessary to work rapidly in order to restore the action of the blood through the system. In about two hours or more, with the assistance of four physicians and what other help we could get, all were restored sufficiently to be taken to their homes, and the most severe cases were kept away from their work only four to five days.

As to what caused the gas to affect so many at this time is unaccountable. From actual experience of over twenty-five years in the business I have never seen nor heard of anything like it before, and in conversation with old molders, they claim they never had. The molding shop had been idle for two days. All ventilators were closed, and the gas after putting on the blast seemed to settle to the earth instead of going to the chimney. It was not our custom to open the ventilators until the room was warmed somewhat from the melted iron; doubtless the gas was all retained in the room.—American Machinist.

WATER IN A CYLINDER.—Referring to rolling-mill engines, there is one other difficulty that comes to mind, and that is, at the full load bringing water over into the cylinder. The *Boston Journal* says it remembers a mechanical engineer, after returning from a visit to a rolling mill in New England, calling attention to this matter. He noticed the engine pounding and asked the engineer in charge what caused it. "It takes so much steam," he answered, "when the load comes on, that it carries a lot of water over with the steam into the cylinder." He didn't believe it would do much damage. "Won't it?" remarked the listener, "I expect some day to hear that that engine has been blown through the partition." It could not have been two months after that the papers contained an account of the blowing out of the cylinder head of an engine at this mill and the resulting death of the engineer. It was the same engineer and the same engine. Water in a cylinder is bound to cause dangerous trouble sooner or later, yet there are many engines supplied with boilers too small where an unexpected addition to the load brings over water with the steam, yet the engineers are feeling safe enough under the supposition that there will not be water enough to cause any damage. An exceptionally high water line will some day cause the trouble.

CRUCIBLE STEEL FOR BOILERS.—The favor with which crucible steel is now being regarded in some quarters as material for boilers is, on the other hand, objected to on grounds that are believed by many good judges to be decisive. It is urged that though this process is for some purposes the best, that is, when steel is wanted in some small quantities of considerable purity, it is a failure when large masses of homogeneous character are required, as is the case in boiler plate, its shortcomings in this respect being due to the process of manufacture, which, as is well known, consists in melting wrought iron, etc., in a crucible holding generally from 80 to 125 pounds, and to obtain a mass large enough to make boiler plate, it is necessary to pour the contents of 20 to 50 crucibles into one mold to form an ingot. As the steel is made in each crucible, it follows that in 30 crucibles there are 30 different kinds and grades of steel in one sheet. The result of this process and of such combination, when subjected to the trying conditions found in a locomotive firebox, is declared to be disastrous in a majority of cases, homogeneity or absolute uniformity of the metal in this service being one of the most important elements found in long-lived fireboxes.

SOME brass condenser tubes in the United States cruiser "Baltimore," after being in service for a year or more, were found to have experienced a peculiar change. In many places the metal was changed to almost pure copper, of a spongy texture, the zinc having entirely disappeared. An investigation showed the probable cause of the failure to have been an electrolytic action between the tin lining of the tubes and the brass, the sea water circulating through the condenser forming the electrolyte. If the coating of the tin had remained perfect there would have been no corrosion; but the foreign bodies, such as mud and grit, carried in suspension through the condenser cut away the tin coating in spots, and it was at these spots that the electrolytic action occurred. A natural conclusion was that had the tubes not been tinned, they would have remained intact.

A TON of anthracite coal averages in bulk from 40 to 43 cubic feet. A ton of bituminous coal occupies from 43 to 48 cubic feet.

Scientific Progress.

Microscopical Research of Metals.

The investigations may be conducted on the actual fractures of the test-specimens, or on specially prepared test-slides. All those treated in the paper are of the latter kind, as using the plain fracture under the microscope does not give very satisfactory results. The author, however, adds a description of the method of employing the simple fractures. The foundation or cement, in which the specimens are placed for polishing, and the polishing material, must be prepared with great care, and varies according to the hardness of the specimen to be prepared. For rough polishing, the author uses fine emery. The fine polishing is done by hand on glass, cast-iron, copper, or lead plates prepared in a special manner.

The polishing powder may be of almost any good polishing material, but has to be extremely carefully prepared, as the grains must all be of one size. To prepare this, the author employs inverted conical glass vessels with a small aperture in the apex of the cone; and the polishing material, being mixed with water, and occasionally shaken up, passes through this aperture, and is divided into different sizes and numbers, according to the time taken to settle. The finest kinds are mixed with spirit or ether. To polish the specimens, which are about one-half inch square and a bare one-sixteenth inch thick, several of them are cemented side by side in a conveniently compact form, and an ordinary glass lens-polishing machine is used to polish them; or they may be polished by hand. The specimens are then taken out and thoroughly cleaned from any particles of cement that may be adhering to them by means of ether.

The coloring of the specimens can be done in various ways, and is one of the principal points to be attended to in microscopical research. The author recommends having several similar specimens under observation at the same time, with different degrees of coloring in each. The coloring brings out the various constituents of the material, and foreign substances contained in the interstices, e. g. ash, etc., and renders them distinct and visible from one another, which they would not be were it not for the coloring matter.

With pig-iron very strong contrasts can be made, but not so with wrought-iron. For photographic work the specimens must be more distinct and clearly marked than for mere microscopical work. The author maintains that the photographs are perfectly easy and simple to obtain, and proceeds to describe with several illustrations the apparatus used in the Berlin Royal Experimental Institute.

In order to obtain a uniformity in the exposure the author takes several trial or test proofs, systematically increasing the length of the exposure with each plate; he then selects the best proof and gives all the following photographs the same exposure as indicated by the test photograph. The developing is treated in a similar way, and by this means the author brings the process down to an almost entirely mechanical method.

Dr. Wedding was of the opinion that sooner or later the microscope would become as indispensable as the test-machine had become, and that all well-equipped laboratories and ironworks would in time possess the necessary apparatus for microscopical research.—Verhandlungen des Vereins für Eisenabnkunde, 1892, p. 67, thro' Proc. Inst. Civ. Eng.

Tannic Acid as a Mordant.

One of the great troubles in using tannic acid, or tannin matters in general, is that on keeping the tannic acid gradually passes into gallic acid, resulting, therefore, in a loss of mordanting power. This change is greatest at moderately high temperatures. As in either the operation of mordanting cotton or in tanning leather a large excess of tannic acid must be employed to effect good results, it follows that there must be a great loss in the operation, owing to the decomposition of the tannic acid into gallic acid. If this could be prevented, then a great saving would result, because the baths could be retained, and would only require new material to restore the original strength. Thus the life of the bath would be prolonged and the consumption of tannic acid reduced.

Some time ago a patent which had for its object the prevention of the loss of tannin, was taken out. The process consists essentially in keeping the baths at a temperature of 40° F., which is done by arranging a number of coils of pipe in the vat containing the

tannin liquors and passing through these coils brine from a refrigerating machine. At the temperature above mentioned the decomposition of the tannic acid is prevented, and so the life of the bath is prolonged.

The question arises, How will the low temperature affect the affinity of the tannin, for the cotton fibre, which appears to be greater at high than at low temperatures, although it is said to be of advantage in the mordanting of the cotton in mixed cotton and wool goods, the affinity of the tannin for the wool being reduced by the process?—The Dyer and Calico Printer.

A DISCOVERY has been made for the manufacture of a strong and flexible substance, as transparent as ordinary brittle glass. The process is as follows: From four to eight parts of collodion wool are dissolved in sufficient ether or alcohol; this solution is intimately mixed with from two to four per cent of castor oil or other non-resinous oil, and from four to ten per cent of resin or Canada balsam. This mixture is spread on a glass plate, and dried by a current of hot air, which, in a comparatively short space of time, transforms it into a transparent, hard, vitreous plate, the thickness of which can be regulated as required. The material thus obtained is said to resist the action of salts, alkalis and acids, and, besides being transparent, is odorless. Its inflammability is much inferior to that of other collodion combinations, and it can be further reduced by the addition of magnesium chloride, while an admixture of zinc-white produces an ivory appearance. It is flexible and almost unbreakable, and any shade or color may be imparted to it. An Austrian engineer named Eckstein claims to be the inventor of this process.

COMBUSTION OF HEAVY HYDROCARBONS. Lighting and heating by heavy hydrocarbons forms the subject of a communication to the *Genie Civil* by M. A. M. Villon, ingénieur-chimiste, who takes exception to the manner in which liquid fuel has hitherto been burnt. He observes that the conditions to be fulfilled for obtaining complete combustion with the heavy hydrocarbons are: (1) A division of the burners so as to obtain a number of jets of flame, between which the air may arrive in sufficient quantity to ensure the perfect combustion of the carbon and hydrogen contained in the fuel; and (2) a reception of the heat produced by the dividend or splitup combustion named above, on a large metal surface covered with water, in permanent contact with the flame, and at the points where combustion takes place; owing to this arrangement, the flames cannot attain a too high internal temperature so that dissociation is prevented, and indeed the temperature of propagation of the inflammation (ignition) need not be exceeded.

ONE of the recent industries added to the already numerous manufactures carried on in Chemnitz, Saxony, is the production of curtains made of India rubber as the main ingredient. The material employed for this purpose consists of 75 per cent of India rubber, five per cent of wool dust, five per cent of pulverized fruit stones, ten per cent of bleached amber varnish and five per cent of bleached leather waste, to these being added, if deemed necessary, a quantity of infusorial earth. The various substances thus named are together worked up with bisulphide of carbon in the most perfect manner into a thick mass, and from this are rolled out thin leaves, which are capable of being decorated with the greatest variety of ornamental patterns, and several of these leaves are combined to form a curtain.

COMPRESSING LIQUIDS.—Some experiments have been made by M. E. H. Amagat in the laws of the compressibility of liquids; deformations of the piezometers were investigated and allowed for, and the pressure carried as far as 3000 atmospheres. The liquids operated upon were ether, alcohol, carbon bisulphide, acetone, the ethyl halides and chlorides of phosphorus. The coefficient of compressibility was in every case found to decrease regularly as the pressure increased. At 3000 atmospheres that of water was reduced by almost one-half its ordinary value, that of ether by two-thirds. This diminution again is greater the higher the temperature. The ratio of the difference of the coefficient to the corresponding difference of temperature decreases as rapidly as the pressure increases.

WHILE paper is being used for dozens of purposes formerly monopolized by wood, or even a harder material, such as car wheels, boxes, barrels, tubs, pails, etc., wood is rapidly driving other ingredients to the wall in the manufacture of nearly all the cheaper grades of paper.

Electricity.

Gas Power for Electric Lighting.

In a paper read before the Institution of Civil Engineers, London, reported in the *Electrical Engineer*, Mr. Dowson stated that an aggregate of 7000 horsepower of gas engines were used in Great Britain for electric lighting, and up to an aggregate capacity of 1100 arc and 90,000 incandescent lamps in Germany. He stated that the varying load factor in central stations was a serious trouble, and he hoped to be able to show that much of the present loss due to fuel, water and wages would be avoided by the use of gas engines. Referring to the central station at Dessau, Germany, where a 120-horsepower gas engine was used, the consumption of gas was 39 cubic feet per kilowatt-hour. In spite of the loss of about 21 per cent in the accumulators used in this station large engines worked more profitably in parallel with them than smaller ones supplying direct without an accumulator. In the suburb of Munich a small plant, producing its own gas, showed a consumption of 3.3 pounds of coal per kilowatt-hour. In another similar small plant, having an output of 1155 kilowatt-hours per week, the consumption of fuel was 2.58 pounds and the cost of the gas, including wages and fuel, was one cent per kilowatt-hour delivered. In a small private installation in France for 650 incandescent lamps and one arc, the consumption was 1.2 pounds per indicated horsepower and 2.7 pounds per kilowatt-hour. It has long been known that with a dynamo run by a gas engine more light could be produced than by burning the gas directly in the burners. With the modern improvements in gas engines he says that the ratio now is 20 to 1 in favor of gas converted into arc lights by means of a gas engine. From compilations made from various sources using town gas, he says the average is 47 cubic feet per kilowatt-hour. When accumulators were used the consumption was less because the engines then worked under full load all the time. At 47 cubic feet and 55 watts per 16 c. p. one lamp required only 2.6 cubic feet per hour, whereas the standard argand burner required five cubic feet. The question of load factor was a serious one in any type of engine, but with gas engines the loss was much less than with steam engines. When a gas engine stops its consumption of fuel stops also, and there is no furnace to maintain, no water to boil at starting. It is, however, desirable that gas engines should be worked as much as possible under full load. In general, he says that it may be assumed that the consumption of coal was more than six pounds per kilowatt when accumulators are used and from nine to twelve pounds when accumulators are not used. In steam engines there is at best always a large consumption of fuel in banked fires and in starting which does no useful work. With gas engines one brake horsepower could be obtained with one pound of anthracite or $1\frac{1}{2}$ pounds of coke, while with steam engines, used in central stations, it must be taken at about 2½ pounds, showing a saving of about 50 per cent in favor of gas when fully loaded. For a maximum of 400 kilowatts three gas generators would be required; they have much less cooling surface than a boiler, contain no water and require no chimney draft. One of these generators loses only six to eight pounds per hour while standing idle. He stated that what is known as the Otto cycle would, in his opinion, have to be altered, especially when generator gas was used. In conclusion he says that in electrical stations supplied with city gas the consumption was about 50 per cent less than that required for the same amount of light from burners. Neither boiler nor firemen were required, no ashes are to be removed, less space was needed, no accumulators were required except to equalize the load and provide an amount for storage. They could be worked in crowded districts close to where the lights were required and where boilers were not allowed. Where generator gas was used the consumption of fuel under full load would be at least 50 per cent less than with steam power.

STORAGE AT CENTRAL STATIONS.—In a recent paper by Prof. Unwin, he calls attention to the fact that the lack of efficiency in central stations is due largely to the fluctuations of the load, and that it could therefore be increased by applying some means of storing. This applies even more directly to power stations for railways. He shows that storage batteries are too unsatisfactory and expensive and that gas-holders are cheapest when gas engines are used. He then explains the method of storing hot water under pressure for generating steam, and gives his

indorsement of the method as being practical and not requiring large plants. As he is a recognized authority, we call special attention of central-station managers to this, as it may play an important part in the future, especially as it is an apparatus which could be added to existing plants without radical changes. As it is not patentable, central-station managers need not fear that some years hence they will get into trouble due to some delayed and uncertain patent litigation.

The First Inventor of the Incandescent Lamp.

A sensation has been caused in electrical circles by the alleged discovery of an inventor of the incandescent lamp who antedates Edison by many years. As announced in our issue of Oct. 6, 1892, the Edison patent, No. 223,898, on the incandescent lamp was sustained in the court of last resort by a decision handed down Oct. 4th, and since that date injunction after injunction has been secured, closing the works of incandescent-lamp makers. But in the suit of the General Electric Co. against the Beacon Vacuum Pump Co. of Boston, the defendants gave the plaintiffs a great surprise by bringing forward affidavits from numerous witnesses alleging that one Henry Goebel, a German instrument maker, invented and made incandescent lamps similar in all essential details to the lamp described in the Edison patent, as long ago as 1855. Goebel emigrated from Germany to the United States in 1848, settled in New York City, and soon began experimenting with electrical apparatus. In the years before the war he operated a portable astronomical observatory, consisting of a telescope 15 or 20 feet in length, mounted on a wagon, which, on pleasant summer evenings, would be stationed in some open space in the up-town streets, uptown then signifying locations no farther north than Union Square or Astor Place. To attract the attention of passers-by, Goebel was accustomed to display two or three of his incandescent lamps, current for which was furnished from batteries placed underneath the driver's seat. It is thus seen that Goebel made no secret of his invention, and until his removal from his shop in Monroe street, which he occupied for more than a score of years, he continued to make lamps and publicly exhibit them. In 1881, soon after Edison's invention was made public, a company known as the American Electric Light Co. was organized to make incandescent lamps, and Goebel was employed to make carbons for the company, and produced excellent work until the company failed. Why the fact of Goebel's anticipation of the Edison patent was not then made public does not yet appear.

The history of Goebel's invention was given in great detail in 28 affidavits, which were filed by the Beacon Co., as its defense in the proceedings for an injunction brought by the General Electric Co. Besides the affidavit of the inventor himself, testimony was taken of several of his children and many of his neighbors, who were familiar with his work, also of Prof. Charles R. Cross of the Massachusetts Institute of Technology and of Mr. Franklin L. Pope. After hearing arguments from the counsel on both sides, the court granted a week's time for the filing of briefs and such further affidavits as each side may desire. It is certain that this remarkable case of prior invention will be thoroughly investigated, and the extent of Goebel's work will be determined.

The new lamp of the Westinghouse Co. also promises to lead to further litigation with the General Electric Co. The new lamp differs from the Edison or common lamp in being made in two parts, like a bottle and stopper. The joint between the two is made by a cement. The Westinghouse Co. probably relies on the fact that the stopper can be made of porcelain or some material other than glass to defend itself from the charge of infringement, as the Edison claim which has been sustained is for a carbon filament in a vacuum chamber made entirely of glass.—*Engineering News.*

AN ELECTRIC LIGHTING APPARATUS FOR MINERS' LAMPS.—An apparatus for lighting miners' lamps by means of electricity has just been patented by Mr. Prestwich, the managing director of the Protector Lamp and Lighting Company, Limited, of Eccles. It avoids any risk of fire in the lamp-room, and any possibility of igniting explosive gases in the mine. The arrangement inside the lamp consists of two small terminals being attached to the extinguishing-plate, in which is fixed a loop of platinum wire, which slightly overhangs the wick. A brass pin, insulated through the bottom, comes in contact with the battery, striking the insulated plate. The platinum wire becomes heated

to incandescence with the electric current, and ignites the wick. The current in the storage batteries is kept up by a full equipment of fittings, in the shape of a small engine and dynamo, a cabinet containing all necessary arrangements, such as armatures, cut-offs, regulators, and storage batteries for the lamp-room, while small accumulators, with safety tops, are charged up from the dynamo, and sent to different stations down the pit for relighting in case a man, by accident or otherwise, should lose his light. The advantages claimed for this arrangement—which can be adapted to any existing type of lamp—are that the lamps can be cleaned and locked up ready for use, and need not be lighted until required, thus saving oil; the lamps can be relighted in any districts in the pit with safety, thus saving time and expense, should a man, by accident or otherwise, lose his light; that the flame cannot be exposed after the lamp has been put together for the day; and that all lamps can be trimmed, etc., for the day, and there are no night shifts required, thus saving a great cost in the lamp-room.

Useful Information.

Heavy Rock Blasting.

In quarrying stone for the Westport harbor works, New Zealand, the charges used were carefully considered, says Mr. John Alexander Wilson, in a paper read before the Institution of Civil Engineers. The stone used was granite, gneiss and limestone, in large blocks. To obtain these cheaply, large blasts were employed, and the rock varied from bedded and jointed gneiss to homogeneous masses of granite. On an average, one pound of dynamite dislodged ten tons of stone, and the total amount of a charge was usually decided on this basis. The separate charges were proportioned in the ratio of the cubes of their least resistance, and this L. R. was divided by 35 for dynamite, 36 for gelignite, 43 for gelatine dynamite, 50 for blasting gelatine, and 12 for blasting powder.

Blasts containing three tons of explosives, and another of seven tons, were each failures, as they broke up the rock too much. It was found that charges of from $\frac{1}{4}$ ton to $1\frac{1}{2}$ tons were the most useful, and this class of blasting hardly answers with a line of least resistance exceeding 40 feet. Beyond that, the elasticity of the rock along this line becomes so great for the resistance of the backfill which the charge works, and instead of throwing the front out, the explosion may merely develop an undulating motion radiating from the charge.

The best results were obtained where the rock had one or more loose ends with a nearly vertical face; a strong toe at the quarry floor-level was usually first removed by hand-blasting before firing the large shot. The length of the adit was made as nearly half the height overhead as practicable, while the most even results were obtained if 15 multiplied by the least resistance was adopted for the interval between the chambers, and even less with irregularly-shaped blasts.

Electricity versus Gas.

Mr. Henry D. Fitch, of Louisville, Ky., presents the following figures showing the effect of electric lighting upon the gas output of a town of 8000 population which he with several others now controls. Mr. Fitch says:

I bought this property in 1889, and after reconstructing it in 1890, I became alarmed over the growth of electricity, and concluded to put in a good alternating electric light plant in connection with my gas works, and, at the same time, push gas for fuel purposes. We supply only private business; the city lights the streets with its own arc plant.

	Illumination. Cubic feet.	Fuel. Cubic feet.
In 1890 we sold gas for . . .	5,943,000	322,000
In 1891 " " . . .	5,545,000	776,000
In 1892 " " . . .	5,780,000	1,488,000

This is taken from consumers' ledger, and does not include leakage. No electricity was sold in 1890—only since March, 1891; and we make no effort to keep consumers from using it. It is probable that if operated by a competition, and with all night service, less illuminating gas would have been used, unless our price for gas was lowered. We get for illuminating gas \$1.90 to \$1.50, net, and for fuel gas, \$1 to 75 cents, net, using separate meters.

WHAT the ideal telescope of the future may do for astronomical science Alvan Clark bids us judge from a comparative survey of its past history and progress. When Galileo, in the early part of the seventeenth century, showed his first telescope,

which magnified only three diameters, to the astonished authorities at Venice, they little dreamed of the possibility of the Lick refractor of to-day. Galileo's first instrument was similar in construction to the ordinary opera-glass. It was no more powerful and was far less perfect. It consisted, in fact, merely of two single lenses, one being convex, and the other concave. Even his last and best telescope, magnifying thirty diameters, was much inferior to some of our spy-glasses.

The Telephone.

The telephone situation is becoming an interesting one. Coincident with the expiration of the various patents on the telephone, the enjoyment of which has been for so long exclusively in the hands of one company, there comes abundant evidence that many other concerns intend to engage in the telephone business as soon as they can safely do so. With the expiration of the patents on the Blake transmitter last month came an extraordinary call for these instruments from all quarters, and when the patents on the Bell receiving instrument terminate, not only will a great demand for receivers spring up, but the event will in all probability signalize the birth of competing telephone companies all over the land. There is every promise of lively times ahead for the telephone business. In the enthusiasm that will ensue there is no danger of going to extremes. The business will thus become demoralized as far as rates and profits are concerned; then an era of consolidation will dawn, and the result will be the formation of trusts and combinations. This is one way of looking at the matter, and as the tendency these times is to consolidate like interests and carry on the business under one management, there appears to be no reason why the telephone should be exempt from the operation of the rule. These are matters, however, that time alone will settle, and those who wish to engage in the telephone business in any capacity whatever need not be deterred from making an effort to succeed simply because of what may happen.—*Electrical Age.*

MOVEMENTS OF A MONUMENT.—According to the newspapers, some curious movements have been observed in the Washington monument. It is well known that all high stone monuments follow the sun, through the expansions which its rays produce on its illuminated side; but in the Washington monument it is found that besides the diurnal movement there is an annual one, the top of the monument describing, in the course of the year, a small circle. A strong wind is found to cause a slight inclination to leeward, showing that either the stone or the mortar in the joints is elastic within certain limits. These movements are detected by means of plumb-lines of wire, to which are suspended heavy lead weights. The weights are immersed in oil to diminish the effect of accidental vibrations, and the wires are enclosed in metal casings. It was recently rumored that the foundation of the monument had sunk, but the fact is that it has risen a few thousandths of an inch. This novel phenomenon is probably due to the expansion of the cement in the concrete, of which, as it will be remembered, the foundation is now practically composed, and it will be interesting to watch its progress.—*American Architect.*

A GOOD ILLUSTRATION of the increase of journal friction with decrease in temperature has been furnished by the gravity railways in the anthracite coal region. According to the press reports, the severe cold weather of the past week has greatly hindered the operation of these roads, some of which form important links in the transfer of coal from the mines to the steam railway lines. The friction of the journals was so much increased that cars had to be started with pinch bars on grades where ordinarily they move off as soon as the brakes are released.

STEAM users should bear in mind that a safety-valve on a boiler should be capable of discharging all the steam that the boiler can make with all other outlets shut. The U. S. regulations call for $\frac{1}{2}$ square inch valve area for each square foot of grate surface; but where the lift of the valve will give an effective area of $\frac{1}{2}$ that, due to the diameter of the valve, $\frac{1}{4}$ square inch valve area per square foot of grate will answer.

THE value of pig iron produced in this country is now greater than the value of gold, silver and copper combined. The value of the coal product is greater than of pig iron. The value of the silver product is less than one-sixth of the value of the other minerals named.

NEW AND VALUABLE BOOKS — FOR — METAL WORKERS.

LANGBEIN.—A Complete Treatise on the Electro-Deposition of Metals. Comprising Electro-Plating and Galvanoplastic Operations, the Deposition of Metals by the Co-tact and Immersion Processes, the Coloring of Metals, the Methods of Grinding and Polishing, as well as Descriptions of the Electric Elements, Dynamo-Electric Machines, Thermopiles, and of the Materials and Processes used in every Department of the Art. Translated from the German of Dr. George Langbein, with additions by William T. Brannet, Editor of "The Techno-Chemical Receipt Book." Illustrated by 125 engravings. In one volume. 8vo., 40s. \$4.00 Price.

BLINN.—A Practical Workshop Companion for Tin, Sheet Iron and Copper Plate Workers. Containing Rules for describing and all kinds of Patterns used by Tin, Sheet Iron and Copper Plate Workers; Practical Geometry; Mensuration of Surfaces and Solids; Tables of the Weights and Strengths of Metals and other Materials; Tables of Areas and Circumferences of Circles; Composition of Metallic Alloys and Solders, with numerous valuable Receipts and Manipulations for everyday use in the workshop. By Leroy J. Blinn. A new, revised, and enlarged edition, printed from new type, and with 170 newly engraved illustrations. In one volume. 12mo., 204 pages. Price.....\$2.50

BRANNET.—The Metal Worker's Handy Book of Receipts and Processes—Being a Collection of Chemical Formulas and Practical Manipulations for the Working of all the Metals and Alloys, including the Decoration and Beautifying of articles manufactured therefrom, as well as their preservation. Edited from various sources by William T. Brannet, editor of "The Techno-Chemical Receipt Book." Illustrated by 63 engravings. Over 500 pages. 12mo., cloth, 6s. 6d., closely printed, containing a vast amount of valuable matter on all the Metals and Alloys, not to be found in any other book in the English language. Price.....\$4.50

BRANNET.—The Metallic Alloys. A Practical Guide for the Manufacture of all kinds of Alloys, Amalgams, and Solders used by Metal Workers, together with their Chemical and Physical Properties, and their application in the Arts and Industries; with an Appendix on the Coloring of Alloys. Translated and edited, chiefly from the German of A. Kopp and Andreas Wildberger, with extensive additions, by William T. Brannet, one of the editors of "The Techno-Chemical Receipt Book," etc. Illustrated by 16 engravings. 12mo., 438 pages. Price.....\$3.00

RICHARDS.—Aluminum. Its History, Occurrence, Properties, Metallurgy and Applications, including its Alloys. By Joseph W. Richards, M. A., A. C., Instructor in Metallurgy at the Lehigh University. Second Edition revised and greatly enlarged. Illustrated by 28 engravings and two diagrams. 611 pages. 8vo., Price.....\$5.00

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Minerals from New South Wales.

J. E. Carne, F. G. S., of Sydney, New South Wales, arrived last week on the Monowai, en route for Chicago, where he will act as assistant to Hon. Arthur Renwick, member of the Legislative Council of New South Wales, in arranging the large mineral exhibit which this, the oldest of the Australian colonies, is making at the World's Fair. Mr. Carne is bringing with him large additions to the samples and exhibits already forwarded, and under Dr. Renwick's instructions will proceed at once to place them in position in the New South Wales' building at the World's Fair.

In conversation with a reporter Mr. Carne said:

"The space of 10,000 square feet allotted to our mining exhibit, although large, will not be nearly sufficient for our requirements, and I believe that arrangements will be made to increase the allowance. We have already sent over 300 tons weight of mineral exhibits, many of them extremely valuable, and there are still several more shipments to follow. Up to now 2300 packages of specimens, ore and mineral samples have been forwarded. Naturally our principal feature will be gold, a metal which we have been producing uninterruptedly for half a century. We shall send this in every imaginable form, from rough wash dirt to highly finished ingots. The precious metal will be shown in every possible manner. There are lumps of quartz showing the reef gold imbedded, and from this it will be seen in every stage of treatment; also alluvial gold in its various shapes.

"Next in importance will come silver. We are exhibiting samples from the big mines at Broken Hill, the most wonderful field in the world—New England mines, Sunny Corner and various other hitherto places of the white metal in New South Wales.

"In addition to showing gold and silver in all its stages, we are designing pyramids, obelisks and other trophies, and we are sparing no pains to make this branch of the mineral exhibit one of the most attractive features of the exposition. A huge lump of silver ore has been forwarded in its native state with the shining metal sticking out of the body, and this will be set upon a pedestal.

"In speaking of the silver from Broken Hill, I cannot refrain from making a few remarks upon this celebrated silver field which has lately been the scene of so much trouble between those two great factors, capital and labor. The original mine, the Broken Hill Proprietary, turned out between May, 1886, and May, 1892, when the labor dispute arose, no less than 36,500,000 ounces of silver and 150,000 tons of lead. It has paid in dividends to the shareholders £278 on each £20 share, which were issued at £9, and on which no calls have ever been made. This means interest at the rate of 3100 per cent on the original cost of the shares, which I consider a tolerably good investment, even for Australia.

"In addition to the precious metals, we are sending several samples of coal from our mines at Newcastle, Bulli, etc., and prominent among the attractions will be some full sections showing the whole width of the seams."

Painting of Structural Iron.

At the last meeting of the Engineers' Club of Philadelphia, Mr. Edward Hurst Brown read a paper on this subject, in which he described the composition of paints for use on wood and metal surfaces, with particular attention to the proper material to use on structural iron work. He said that it is very essential that the iron itself should be absolutely free from rust, as the latter will spread from a point under the paint if there be the slightest chance for it to do so, flaking off the paint and thus gradually exposing the bare surface of the iron to the destructive action of oxygen in the presence of water.

The iron should be prepared by removing the scale with a stiff wire brush and destroying the rust by a pickle of dilute acid, which must be afterward washed off before applying the paint. For use on iron exposed to changes of temperature, to gases or moisture, a paint was recommended called "anti-rust," which is manufactured especially for this purpose. Sections of iron pipe were shown which had been painted with this material and with other kinds of paint, and exposed to various severe conditions of temperature and oxidizing gases.

The writer considered it very important that specifications for painting engineering constructions should be carefully drawn and strictly adhered to, even to the specification of definite brands or makes of materials. The engineer should experiment, in order to determine the best paint to use under given conditions, or should seek advice on the subject from those who have made its manu-

facture and its wearing qualities the study of their lives. It is poor economy to use any but the best material obtainable, the saving in the first cost being more than counterbalanced by the labor of renewing the paint in a comparatively short time.

THE FRANKS OF LIGHTNING.—The pranks of lightning in connection with street railway apparatus are particularly vexatious, says *Engineering Magazine*. One peculiarity is that the "fluid" always seeks to strike at the very heart of the system, the station generator, and if it succeeds in disabling this the entire system is brought to a standstill. In some parts of the country, when a violent thunderstorm makes its appearance, it is a common practice to shut down the dynamo, remove the trolleys from the wires and await with as much patience as may be the subsidence of the disturbance. It is stated that on one line, where an account has been kept, the loss of revenue due to compulsory stoppages during thunderstorms amounts to over \$6000 per year. An ingenious form of lightning arrester recently devised to overcome this difficulty consists of a coil of wire inserted in the main circuit and fitted with a number of discharging circuits connected at different points throughout the coil, leading to electrodes immersed in a tank of running water in electrical connection with the earth.

The financial value of technical training in the United States is illustrated, says the *New York Sun*, by the fact that engineer officers of the navy often resign their commissions to accept profitable employment with large manufacturing concerns. A man armed with the training and technical education of a naval engineer can command in civil life a salary from two to five times as great as his pay in the navy. Engineers must serve for the greater part of their lives at less than \$500 per year, and the number to pass \$6000 must be exceedingly small. The plums that await such men in civil life are of a sort to prove a serious temptation to all who feel the necessity of a large income, and it is only the ease and dignity of a naval life that keep skilled engineers in the service.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Sampling Works for Sale.

The works are situated at Daggett, Cal. In the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower Engine and 45-horsepower Boiler with Ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. OILREPT, 1914 Stockton St., San Francisco.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursions through to Boston leave every Tuesday. W. A. BISSELL, 850 Market street, Chronicle Building, San Francisco.

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoops, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Denison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co., H. A. W. TAYLOR, Pres.; L. S. G. DENISON, V. Pres.; H. A. JONES, 2d V. Pres.; P. O. OOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Sec'y; PETER McCOURT, Treas.; W. L. COOPER, Eng.

TRADE MARK.

On the D. & R. G. R. R., near the R. R. Depot.

THE CASSEL GOLD EXTRACTION CO., Limited, Scotland. Also in Australia, South Africa, New Zealand, Queensland, Etc.

General Office of Company:

Rooms 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mine in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingston Old Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Old Extraction and Power Co., Colo.; Calumet Old Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Old Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercer Old Mining Co., Fairfield, Utah; Champlin's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned King and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Co., Old Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the MacArthur-Forrest process.

We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process.

If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubes especially constructed according to our diagrams, for filtering, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ores for this process are the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,

T. L. WISWALL,

P. O. Box 926. Gen. Mgr. and Secretary.

DIAMOND ROCK DRILLS.

For prospecting mineral veins and deposits, Boring Vertically, Horizontally, or at any angle to any desired depth, taking out a Cylindrical Section or Core the entire distance, showing exact character, and giving a perfect section of the strata penetrated. Also for Boring Artesian Wells perfectly straight, round and true. Machines for Channelling, Gidding and other kinds of Quarry Work, Shaft Sinking, Tunneling, Mining Railroad and all classes of rock-boring. Manufactured by

THE AMERICAN DIAMOND ROCK BORING CO.,

15 CORTLANDT STREET, NEW YORK.

P. O. Box 1442.

Pacific Chemical Works.

HENRY G. HANKS,

Practical and Industrial Chemist, Assayer
and Geologist.

718 MONTGOMERY ST., - SAN FRANCISCO.

Will report on the condition and value of any mining property on the Pacific Coast. Rare Chemicals made to order. Instructions given in Assaying and Practical Chemistry.

continue to extract some ore from the old stopes, eight floors up in the upraise No. 6 carried up from the main northwest drift; also from the old stopes in working north from the crosscut run west from the northwest drift. The winzes started in this west crosscut, in old timbers, has been sunk 14 feet, and some fair-grade ore has been extracted therefrom. Have extracted during the week from the 1500 level stopes and 1650 southwest drift openings and raised to the surface 546 cars of ore about 540 tons. Shipped to Morgan mill 803 1990-2000 tons of ore. Average assay value, per railroad car samples, \$26.37. The average assay value, per battery samples, of all ore worked at the mill during the week (705 tons) was \$23.41 per ton.

OPHIA.—1465 level.—Have continued the work of cutting out a chamber in the north lateral drift on the sill floor of this level, at the point where connection was made with this drift by the upraise which was carried up from a point 99 feet below on the north side of the crosscut run east from the drift run south from the Mexican into the Ophir ground.

MEXICAN.—On the 1465 level the drift run north from the crosscut run east from the bottom of the winze sunk 101 feet below the sill floor of this level, near the south line of the mine, has been advanced 20 feet; total length, 553 feet, continuing in porphyry and some clay.

UTAH.—340 level.—The south drift from the main west drift at a point 595 feet in from the shaft has been extended 22 feet; total length, 104 feet; continuing in porphyry, clay and fine lines of quartz.

SIERRA NEVADA.—West crosscut No. 2 from Kenosha tunnel, started from north drift, 800 feet in, has been advanced 29 feet during the past week; total length, 700 feet; face is in porphyry with stringers of quartz. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 23 feet during the past week, making the total distance west of the shaft 2934 feet; face is in clay and porphyry.

UNION SHAFT.—The joint Union Con. and Sierra Nevada west drift, 900 level, has been advanced during the past week 23 feet, making the total distance west of shaft 2934 feet; face is in clay and porphyry.

ANDAS.—On 420 level have been timbering north drift from east crosscut No. 1, north. Work resumed in face of drift.

GOULD & CURRY.—200 level: During the past week, west crosscut No. 5 started in northwest drift, 432 feet from main west drift, has been advanced 19 feet, passing through porphyry, seams of clay and stringers of quartz; total length, 309 feet. On the Suro tunnel level the joint east crosscut with Best & Belcher Company from the joint north drift has been extended 20 feet; face of same in porphyry.

BEST & BALCHER.—200 level.—During the past week the west crosscut No. 1, started in northwest drift, 170 feet from our south line, has been advanced 20 feet, passing through quartz giving low assays; total length 57 feet. 900 level.—All work on this level during the past week has been on repairs. Suro tunnel level.—On this level we have taken charge, jointly with the Gould & Curry Company, of the north drift which was run by that company and the Savage to the Gould & Curry south line. At present we are running an east crosscut to make connections with the Gould & Curry winze carried down from the 1600 level. When the connection is made it will secure good ventilation and enable us to prospect the Gould & Curry and Best & Belcher ground going north.

HALE & NOACROSS.—We continue retimbering main shaft above the 400 level. Main Incline.—Are making the necessary repairs. 1400 level.—We continue retimbering the main north drift on this level. 1800 level.—West crosscut No. 1 from the main south drift was advanced 17 feet; total length, 130 feet; face in porphyry. West crosscut No. 3 from main north drift was extended 20 feet; total length 335 feet; face in porphyry with small seams of quartz. West crosscut No. 4 from main north drift was advanced 19 feet; total length 176 feet; face in porphyry and streaks of quartz.

CHOLLAS.—The north drift from the south line, 550 level, is out 168 feet; face in low-grade quartz. Are repairing north drift, 750 level and retimbering the two north compartments of the main shaft above 930 level. Have resumed work in the east crosscut, 160 feet south of north line, 930 level, which is now out 254 feet; face in porphyry.

POTOSI.—South drift, 30 feet back from the face of east crosscut from the Potosi winze, 930 level, is out 39 feet; face is in porphyry and stringers of quartz. South drift from top of raise, 1000 level, is out 152 feet; face is in porphyry and stringers of quartz. The north drift from top of raise, 1000 level, is out 98 feet. Have passed through some good ore during the week; face is in stringers of quartz and porphyry. The north lateral drift from the bottom of the Potosi winze, 1800 level Ward shaft, is out 30 feet; face in quartz and porphyry. Extracted and sent to the mill the past week 490 tons and 1750 pounds of ore from the 550, 950 and 1150 levels. Milled during the week 527 tons; on hand at mill, 100 tons and 1000 pounds. Average battery assays, \$22.53. Average car sample assays, \$23.64. Shipped to U. S. Mint, Carson, 239 pounds of crude bullion.

BULLION.—The west crosscut from the north-west drift, 300 feet south of north line, 1800 level of Ward shaft, is out 288 feet; face is in quartz and porphyry.

APAX.—Did not sink No. 1 winze this week, as the prospects for a bonanza are better as we proceed northward. Will send the drift farther north before sinking.

WAAN SHAFT.—The connection from the pressure pipe, 1800 level, to the blowers is completed. The west crosscut from the north-west drift, 300 feet south of the Bullion north

line, 1800 level, is out 288 feet; face is in clay and porphyry. The north lateral drift from the bottom of the Potosi winze, is out 30 feet; face is in quartz and porphyry.

ALPHA.—The connection from the pressure pipe, 1800 level of the Ward shaft, with the blowers, is completed.

EXCHAUQUER.—The connection from the pressure pipe, 1800 level, Ward shaft, with the blowers, is completed.

OCCIDENTAL.—The east crosscut, No. 5, from the end of north drift, 750 level, is in 30 feet, and has reached the clay wall. Some bunches of good ore were found in the crosscut near the clay wall. Have resumed driving the main north drift. The crosscut from the bottom of No. 2 winze, in south drift, is in 10 feet in ore of fair quality. The Zsidig drift, Suro tunnel level, has been extended 12 feet in hard porphyry; total length, 825 feet.

NEW YORK.—The winze on the 650 level is down on the stopes 91 feet; bottom is in quartz, some of which gives fair assays. The west crosscut, from the southwest drift from the shaft, 850 level, is out 54 feet; formation, soft porphyry.

SILVER HILL.—The southeast drift, 450 level, has been advanced during the past week 5 feet, through hard porphyry; total distance from north line, 52 feet.

KENTUCKY.—From the stopes on the 160 level we continue to extract from two to three tons of ore per day of an average value of \$37 per ton. The south drift from the Jacket east crosscut on the 1100 level was extended 24 feet; total length, 100 feet. The face is in ore assaying from \$5 to \$20 in gold.

Tuscarora District.

NAVAJO.—*Times-Review*, Feb. 17: Work for the week has been confined to the stopes above the 350-foot level, which are without material change.

BALLA ISLA.—The stopes above the 250-foot level are looking about the same. Line crosscut, same level, extended 10 feet, cutting a vein which shows a little good ore.

NORTH BELLE ISLE.—The stopes above the north 300-foot level still yield high-grade ore, but the vein is small. The stopes above the south 300 are yielding a little good ore.

ARIZONA.

THE COMMERCIAL COMPANY.—*Arizona Silver Belt*, Feb. 14: Prof. Jas. Douglas and Miss Douglas took their departure on Tuesday. During his short stay here, the Professor inspected the principal claims belonging to the Commercial Mining Co., and outlined the course to be pursued in relation to the company's interests in Globe for the immediate future. We regret to learn that the Commercial Company has decided not to prosecute active work on their claims in Globe District, at least until the construction of a railroad to Globe is well under way and its completion assured. Prof. Douglas, we understand, does not take a hopeful view of the copper market, which probably influenced his decision. Dr. Alexander Trippe resigned as superintendent some time ago, and will be succeeded by E. H. Cook, who will act as agent of the company here and will have direction of the work on the Buffalo group and Buckeye mine. Mr. Philip Oates will continue in charge of all the other claims belonging to the company. Prof. Douglas received a telegram on Monday announcing the destruction by fire, Feb. 5th, of the Commercial Mining Co.'s reduction works at Copper Basin, Yavapai county, consisting of smelter, chlorination and leaching works. The works were closed owing to a scarcity of water, only a watchman being in charge, and the origin of the fire cannot be accounted for, unless it was incendiary. It was a very complete plant, valued at \$125,000 or more, and on which there was no insurance.

OLD DOMINION.—Y. Aguirre, who does the largest freighting business on the Wilcox and Globe road, came in yesterday in advance of his six large teams loaded with coke for the Old Dominion Copper Co. He reports the road in fine condition, but feed very scarce. Shipments of Old Dominion copper have commenced from Wilcox. Only two shipments were made from that point during the last half of 1892, and two or three million pounds had accumulated.

MOHAVE NOTES.—*Miner*, Feb. 18: Brawn's teams brought in eight tons of concentrates from the C. O. D. mine one day this week. Mix & Jackson have discovered some fine-looking ledges in Minnesota district, a few miles west of the Jennie mine. Newton Snell is still prosecuting work on the Antelope mine. Wallapai mountains, and is taking out ore of exceeding richness. Jas. Penberthy is again at work on that old standby, the American Flag, among the murmuring pines of the lofty Wallapais. Messrs. Maloney, McGregor and John Campbell are taking out some very rich rock from their lease on the Horn Silver, Eugene camp. Our old friend Thomas Steen has encountered a large body of rich ore in the new workings of the Jennie mine, Minnesota district. R. G. Patterson had one ton of ore from the Prince Albert mine worked at the sampler this week. It netted the owner over \$1000. Shepherd & Smith have four men at work on their Horn Silver mine, Eugene camp, and the property is developing into one of the finest mines in Minnesota district. Quite a number of prospectors are scouring the hills in the vicinity of Eugene camp in the search for the precious metals, and quite a number of good-looking ledges have been discovered. Messrs. Williams, Hamblin and Chidister are taking out rich gold ore from the Lucky Boy mine, Minnesota district, and have enough ore in sight to insure them at least a World's Fair stake. Frank Hamilton, Richard Cleve and H. P. Cox have out several tons of good ore on the dumps of the Mississippi mine, Wallapai mountains. They expect to make a load

shipment next month. Messrs. Frank Allen and Tom Shannessy have leased a portion of the Greenhorn mine, near Eugene camp, from McGregor & Shepherd, and have commenced work with a good body of ore in sight. P. R. Washington is leaching at Jennie Springs, Minnesota district, on ore from the Horn Silver and Silver Flake mines, and seems to be doing a good deal of good for himself in the way of a World's Fair stake. Henry McLaughlin was in town from the Minnesota mine Thursday. He informs us that John Barry's little mill at that place is turning out concentrates at a lively rate and will shortly ship a quantity to the sampler. Conkey & Tyler had two tons of ore from their lease on the Prince Albert mine, Indian Secret district, run through the sampler yesterday. We were unable to learn the exact figures, but suffice to say it reached into the thousands. Dowd & Detricks have taken a lease on the Crownlet mine, Indian Secret district, and they have encountered a beautiful body of 400-ounce ore on the 100-foot level they are running east from the bottom of the shaft. This property is owned by Messrs. Conkey, Tyler and Galigher, and bids fair to become one of the mines of that district.

IDAHO.

GERMANIA BASIN.—*Ketchum Keystone*, Feb. 18: W. S. Feagley arrived in Ketchum last Saturday direct from Germania basin. He reports the lessees in that camp all doing well. The lessees of the Parnell mine, owned by Daniel Hawkesworth, have taken out 60 tons of high-grade ore, and have enough more in sight to keep them employed for months. Ole Opland, lessee of Fred Phillips' Idaho mine, has taken out about 20 tons and is working in a body of ore that seems almost inexhaustible, and of high grade. Charles Challis & Co. have been working on a flume since '85 to carry water to work their placer in Kelley gulch, located in Stanley basin. The flume is large, being 2500 feet long and 32 inches wide. They made a clean-up last summer which was satisfactory, and a run this summer will bring them out all right.

MONTANA.

GOLD MINES.—The prominent gold mines near Philipsburg are the Alps, on Harvey creek, and the Royal Gold at Medhurst. Both of these properties are now undergoing vigilant explorations for the purpose of determining what class of reduction works will be necessary to handle the ore successfully. Both have immense ore deposits in sight, and both have small mills that pay very well.

THE SUNAISE MINING CO., a Philipsburg corporation, owns 14 claims south of Henderson gulch—an early-day placer camp—about 12 miles from this city. It is claimed that the Sunrise people own the ground and ledges of gold-bearing rock from which the famous Henderson placers were washed; but however this may be, they have running through their ground a gold-bearing quartz ledge of great width, but as yet unexplored. The work done by this company has been confined principally to the development of silver lodes on another part of their ground. The silver ledge is very similar in every way to the Combination, the formation being the same, and the assays show from 35 to 70 ounces silver and from \$3 to \$5 per ton gold. The Sunrise is one of the coming properties.

OREGON.

GREENHORN.—*Bedrock Democrat*, Feb. 18: The Stevenson, Scott & Smith Co. is making arrangements to erect two arrastres in the spring to work the ores taken from its mines near Susanville. The Esple is informed that its Quartz gulch ledge is showing up well and that it has a large quantity of rich ore taken out. Smith Bros., of Susanville, have two hands at work on the Princess mine. They have been doing some repair work on the outside, but are at present ready to enter the tunnel, with a view of tapping the ledge at a short distance. The Smith Bros. have expended considerable money in developing the Princess ledge, and have hopes of getting out some good ore this winter. A letter recently received from Jack Coyle in Greenhorn, is to the effect that men are daily arriving at Granite, and that the outlook for a big boom in that camp during the coming year is bright indeed. Mr. Coyle has not had great faith in that camp in times past, but now believes that it will soon become the largest camp on the Pacific coast. Let's all hope that Mr. Coyle's predictions will prove correct. Extensive operations are about to be put in force toward a thorough development of the Cabell mine. Mining engineers have already been to look over the property with a view of opening the mine so the ore can be obtained in large quantities to keep the mill at steady work. If the intentions of the company are carried out, there will be a large force of miners employed to successfully handle the work that will be necessary for the fulfilling of their plans. The Cabell mine is considered to be one of the representative mines of the Northwest. Extensive work has already been done, and up to the present time the ore obtained has proved the great value of the property. There is no doubt that the present owners are men with means, and that a large amount of capital will be expended for a thorough test of its worth. All miners on Greenhorn are still progressing with their work with very gratifying results.

WASHINGTON.

THE SWANK MINE.—*Cor. Ellensburg Capital*, Feb. 18: The last heavy snow assures plenty of water, and plenty of water means plenty of gold. The coming season without doubt means the most prosperous ever seen on the Swank. The Delig & Powers hydraulic claim is all rigged up. The pipe, giant and flume have all been refitted and it is now one of the best outfits in Kittitas county, and, if handled right the coming summer, is going to make a big re-

turn for the fortunate owners. B. C. Pilcher, of Port Townsend, proprietor of this old Black claim, is back in camp getting ready for the next season's run. It is not necessary to say anything of this well-known property. The \$4000 taken out last summer with only \$300 expenses speaks for itself. The Green Tree Co.'s claims, bonded to Spokane parties, will not run the coming season unless the said Spokane parties pay their debts contracted last season for hired help and material furnished. The prospects are that this is going to be the greatest season for placer mining ever seen on the Swank. Quartz mining has been at a standstill, owing to the snow and cold weather, except a few claims. T. J. Vinton has been working on the Homestake part of the winter. He had several assays made in Ellensburg last week. The results are about the same as those made last summer, \$14 per ton free gold. The owners of the Buck Horn had some ore tested by Mr. J. C. Hubbell, the assayer, of Ellensburg. The result was \$75 per ton free gold.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING FEB. 14 1893.
491,629.—HAARDER AND REAPAR—Abel & Daly, Maxwell, Cal.
491,792.—BUTTER-MOLDING MACHINA—P. O. Andressen, Ferndale, Cal.
491,696.—LATCH AND LOCK—J. E. Armstrong, Santa Cruz, Cal.
491,866.—TRANSMITTING GEARING—H. C. Behr, S. F.
491,632.—CULTIVATOR—C. Bizi, Selma, Cal.
491,514.—DANTAL FORCEPS—C. E. Blake, Sr., S. F.
491,515.—DANTAL FORCEPS—C. E. Blake, Sr., S. F.
491,516.—DENTAL FORCEPS—C. E. Blake, Sr., S. F.
491,517.—DENTAL FORCEPS—C. E. Blake, Sr., S. F.
491,518.—DANTAL FORCEPS—C. E. Blake, Sr., S. F.
491,519.—DANTAL FORCEPS—C. E. Blake, Sr., S. F.
491,834.—COFFEE URN—F. E. Browne, Los Angeles, Cal.
491,536.—PENOL SHARPENER—G. Diez, Santa Clara, Cal.
491,883.—PAPER HOLDER AND CUTTER—E. J. Gillespie, San Jose, Cal.
491,807.—HORSE DETACHA—I. A. McCaslin, Santa Clara, Cal.
491,855.—GAS ENGINE—J. W. Raymond, S. F.
491,814.—LOOK NUT—G. C. Richards, Sisson, Cal.
491,815.—HORSE DETACHA—Geo. Riley, Vallejo, Cal.
491,955.—FISHING RAIL—Jos. Singer, Los Angeles, Cal.
491,863.—SAED PLANT—G. A. Stine, Spokane, Wash.
491,612.—CAA COUPLEA—W. W. Swank, Seattle, Wash.
491,932.—DENTAL FORCEPS—A. Whitlock, San Bernardino, Cal.
22,223.—DIGN FOR SPOON—Birmingham & Grandjean, S. F.

The following brief list by telegraph, for Feb. 21 will appear more complete on receipt of mail advices:

San Francisco—James W. Kerr, rope shaver or wheel; Andrew W. Livingston, rans-riding machine; Max Sichel, producing dental cement; Albert W. Smith, constructing armature cases for electric motor and dynamo. California—Charles W. Barrett, Lemore, lemon squeezer; Fred M. Brawn, Oakland, condenser for electric railway; George W. Chambers and B. F. Gruver, Bitter Water, retractor for carriages; Seth D. Coombs and R. A. Frates, pinbar; William P. Miller, Redding, recovering precious metals; Peter L. Younger, Oakland, brick kiln.

Oregon—John S. and C. E. Baker, Newburg, cooking and smoking apparatus; Julius Graaf and J. M. Lemore, Portland, extension table.

Washington—L. C. Deiman, E. Wilson and C. Eaton, Spokane, recovering gold; Robert Sears and L. B. Lindsey, Spokane, bridle bit.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PAAS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LATCH AND LOCK.—John E. Armstrong, Santa Cruz, No. 491,793. Dated Feb. 14, 1893. The object of this invention is to provide simple and effective means for locking and releasing the main bolt, and to provide for the convenient location of the locking device in the knob, spindle and the key-way in the knob, whereby the latter may be easily found, and the necessity for a separate key-way and escentcheon avoided. The patent is an improvement on one granted to the same inventor, Sept. 27, 1892.

HOASE-DETACHA.—Irving A. McCaslin, Santa Clara, assignor of one-half to James A. Allen. No. 491,807. Dated Feb. 14, 1893. This is one of that class of horse-detachers in which the thill-coupling bolts are adapted to be withdrawn, to disconnect the shafts from the coupling clips, by means of a power device arranged at a point between the opposite bolts, and adapted to be operated by suitable connections from the vehicle above.

ADJUSTABLE MAP OR CHART STAND.—J. H. Kanfman, Marysville. No. 491,358. Dated Feb. 7, 1893. This is one of that class of stands

for suspending maps and charts in which a horizontal arm or bar, which carries the map or chart, is supported upon a vertically adjustable rod, mounted in a hollow standard. The object of the invention is to provide a stand adapted to be vertically adjusted to different heights, and to be adjusted axially to different angles, said stand being adapted to receive successive supporting arms for different maps or charts, and to permit the arm with its map or chart, when in place on the stand, to be turned from a horizontal position, in which said chart can be exhibited, to a vertical position in which it is out of the way.

BUTTER MOLDING AND CUTTING MACHINE.—P. O. Andressen, Ferndale, Humboldt Co. No. 491,792. Dated Feb. 14, 1893. The invention relates to butter-manipulating machinery, having for its object the molding and the cutting of the butter into squares. The invention consists in the novel sectional bed for the butter, the means for periodically advancing said bed and feeding the butter to the cutters, the means for relieving the advanced end of the butter from the underlying bed and cutting said end both lengthwise and crosswise into squares, the means for operating the cutters, and the means for separating and discharging said squares.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 23, 1893

Silver Product in 1892.

An epitome of the Mint Director's Report for 1892 with reference to the precious metals was published in the local papers on the 21st. The figures were somewhat muddled, and there was an absence of harmony in the mixture between the several papers, no two publishing the same figures. As near as we can decipher the statements, the product of gold in the United States for the calendar year of 1892 was, in round numbers, \$33,000,000, while the product of silver was \$8,000,000 fine ounces, of the commercial value of \$50,750,000, or within a fraction of 87½¢ per fine ounce. The value of the gold was the same as the year before. The product of silver was 330,000 ounces less than in 1891.

Though silver shows a falling off of only 330,000 ounces, and while the coming value of the quantity produced is only affected to that extent thereby, the commercial value shows a considerable falling off. For example, the commercial value of the 58,330,000 fine ounces produced in 1891 was \$57,630,000, whereas the commercial value of the 58,000,000 ounces produced in 1892 was only \$50,750,000. With only a decrease of 330,000 ounces of product, there has been a difference of \$6,880,000 in the value of the total product. This decrease in value has made an important item in the welfare of more than one mine where the cost of production left but little profit in 1891. As a result, several mines have been obliged to suspend operations to the great detriment of property and labor interests.

The silver product of the United States since January 1, 1878, and the gold value of the same, have been as follows for each calendar year:

	Fine Ounces.	Commercial Value.
1878.....	34,960,000	\$10,270,000
1879.....	31,550,000	35,430,000

At present prices, it is safe to say the limit of silver production in the United States has been reached. A better guarantee than 85¢ per ounce is needed as an incentive to further development along this line. Of course there are some mines that can make a profit on silver at 50¢ per ounce, or even 25¢ per ounce. An investigation made a year or two ago revealed the fact that silver could be produced as low as 9¢ per ounce, and in one mine it was produced without cost, as the profit on the lead in which the silver was found more than paid the expenses of operation. But taking the business as a whole, under existing circumstances, silver must average over 75¢ per ounce to keep any considerable number of mines open. The competition of Mexico must ever act as a depressing influence in the business of silver-mining in this country.

Mining Dividends in January.

The Engineering and Mining Journal reports \$1,015,900 paid in January by 28 mines in the United States, including \$500 from the Belden mica mine in New Hampshire, \$12,500 from the Great Western quicksilver mine of California, \$20,000 by the Minnesota iron mine in Minnesota, \$20,000 by the Napa Consolidated quicksilver mine of California and \$15,000 by the Pacific Coast borax mine of California. The remainder was from gold and silver mines, including \$75,000 from Alaska and \$88,000 from six mines in California. There was \$97,500 from the Seven Stars mine of Arizona.

Mining Share Market.

The principal topic of conversation in connection with Comstock mines is the proposition to drain the lode, now being considered. At a meeting of managers and superintendents of Comstock mines, held at the offices of James L. Flood and John W. Mackay in the Nevada Block, there were present John W. Mackay, James L. Flood, D. B. Lyman, A. C. Hamilton, H. M. Gorham and others. A plan to reduce expenses and to begin pumping the water out of the lower levels, with the view of resuming deep mining, now that the upper levels have been well worked out, was considered. D. O. Mills, H. M. Yerington and others who represent railroad and other interests which are dependent upon the Comstock mines for support, were not present at this meeting. After a general discussion of the necessities of the hour, it was deemed prudent, before calling upon the stockholders of the mines for the money required to pump out the lower levels, to get some accurate data regarding the feasibility of the scheme, and D. B. Lyman, W. E. Sharon, R. P. Keating and A. C. Hamilton were employed as a committee to employ expert engineers to furnish data and estimates of the cost of pumping under certain conditions.

"You see," said John W. Mackay to the reporter, after the meeting had adjourned, "we don't feel like going into this pumping business until we thoroughly understand what the cost is to be. If we find it feasible and that it will not bankrupt the companies we will try it; otherwise we will drop it and let matters take their natural course. What we want are some statistics upon the subject, and it will take three or four weeks to get them. For my part, my only interest is in keeping miners employed, for times on the Comstock are hard indeed."

It is understood that after the committee appointed has obtained its statistics as to the cost of pumping, the miners' unions at Virginia City and Gold Hill will be asked to submit to a reduction in wages, which are now \$4 per day, and that the railroad, water, wood and other interests will be requested to make corresponding reductions, so as to offset the cost of pumping.

To a reporter W. R. Eckart, the engineer secured by the Pumping Committee to obtain the data to be embodied in its report, said: "An impression prevails that we can get our report on the feasibility of pumping out the lower levels of the Comstock ready in two or three weeks. This is wrong. Please inform the public that it will take two, and very likely three months, before we can lay the matter before the companies in proper shape. Our task is gigantic, and even at that is only a preliminary one,

before any pumping can be done, itself a great undertaking. I go to Virginia City some day next week and meet the committee there. Our first work will be to ascertain how much water was being pumped from the lower levels years ago, when all the pumps were in operation; that is, when they were boding the water down in the bottom of the mines. We will also have to ascertain the cost of that work. To do that we will have to go carefully through all the old books and records. Then we will have to compute the quantity of water which now flows every shaft, winze, drift, crosscut and other openings in the entire lode, and make allowance for the inflow, the situation of the ground, and the formation of underground lakes caused by caves. Having secured this data, we will have to decide where the pumps can be placed so as to work to the best advantage, and then will come the question of what appliances it is best to use and the cost. What I have enumerated are only a few details of our great work, and the public will see that we cannot do this in a hurried way. These and many other details secured, we shall make up our report, and then it is for the stockholders to judge whether it will be best to pump or allow matters to remain as they are."

Situation Wanted.

Young mining engineer, with seven years' experience in California mines, would like an engagement with good mining company. Understands assaying, surveying, bookkeeping and general management of mining properties. Best of references. Address J. K., Box 2517, San Francisco.

Assessment Notices.

FALL RIVER CONSOLIDATED GOLD QUARTZ MINING COMPANY. LOCATION OF principal place of business, San Francisco, Cal. Location of works, Plumas County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 3d day of February, 1893, an assessment (No. 10) of two cents (2¢) per share, was levied upon the Capital Stock of the Corporation, payable immediately in U. S. Gold Coin, to the Secretary, at the office of the Company, 313-315 Front St., San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 23d day of March, 1893, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the 17th day of April, 1893, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors,
ADOLPH LORENBACH, Secretary.
Office, 313-315 Front St., San Francisco, Cal.

SUPERIOR MILL AND MINING COMPANY. LOCATION of principal place of business, San Francisco, Cal. Location of works, Placerville, El Dorado County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of February 1893, an assessment (No. 1) of five cents (5¢) per share was levied upon the Capital Stock of the Corporation, payable immediately in U. S. Gold Coin, to the Secretary, at two offices of the Company, Room 2, No. 323 Front St., San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 20th day of March, 1893, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 5th day of April, 1893, at 1 o'clock P. M., to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors,
I. N. WITHROW, Secretary pro tem.
Office, Room 2, No. 323 Front St., San Francisco, Cal.

PUBLIC SALE

— OF A —

SILVER REDUCTION PLANT

THE TOMSTONE MILL AND MINING COMPANY, having no further use for its mill and furnace at Charleston, will sell at public sale, on the property,

TUESDAY, MARCH 21, 1893, AT 3 P. M.

To the highest bidder for cash: All of the property known as "The Charleston Mills," real, personal and mixed; consisting of one 20 and one 15-stamp silver mill; one 25-ton water-jacket lead smelter; dwelling house and other buildings; and including the land, mine, ditch and water right pertaining thereto; situated on the San Pedro river, nine miles from Tombstone, Cochise county, Arizona.

Terms of payment will be made known at the sale and ample time allowed to investigate the title to the property.

By order of the Board of Directors of the Tombstone Mill and Mining Company,

W. J. CHEYNEY, Secretary,
Tombstone, Arizona.

WORLD'S FAIR REDUCTION.

San Francisco Pioneer Screen Works

JOHN W. QUICK, Proprietor.

GREAT REDUCTION IN MINING SCREENS UNTIL the opening of the World's Fair. Perforated Sheet Metals, Steel, Russia Iron, Zinc, Copper, Brass, etc. Mining Screens a Specialty.

An Abnormal Borax Deposit.

Nearly all the boracic deposits heretofore discovered have been found in the form of incrustations on the surface of marshlands, of nodules buried beneath the surface or of crystals imbedded in the mud at the bottom of shallow lakes. In a few instances these deposits are found interstratified with layers of earth and rock, the entire formation being in a horizontal position, as seen at several points in Death valley. But only in the Calico district, San Bernardino county, does one of these boracic deposits occur in the form of a regular vein, so uptilted that it requires to be exploited after the manner of a quartz or other ore-bearing lode. The cut here given shows the manner in which this deposit, standing between the walls of slate, is opened and worked.

This deposit, the property of the Pacific Coast Borax Company, is located on the southeasterly slope of the Calico mountains, or rather on a northerly spur of that range. This lode, which outcrops at intervals for nearly three miles, has an east and west course and a southerly inclination. The slate walls are inclosed in sandstone, superimposed upon which is a brecciated rock, evidently of volcanic origin. The crude material here consists of that variety of the borate of lime known as Colemanite. It is of a vitreous adamantine luster and exceedingly rich in anhydrous boracic acid. The contents of the fissure is six feet thick, and at a depth of over 200 feet holds this proportion, nearly pure mineral. The deposit has been opened by several shafts standing 100 feet apart, these being connected by drifts and levels. The material being easily broken down, but a small working force is required in the mine. All that is abnormal about this deposit of borax is easily accounted for. Originally, it was, no doubt, deposited at the bottom of a lake, where,

later on, great floods brought down a quantity of sediment which covered it up. In course of time this sediment having been converted into rock, the whole was then lifted up by some great convulsion of nature and left standing at its present angle, this movement having been most likely of a seismic character.

In the early history of the borax industry the works put up for the manufacture of this salt were of a very rude and primitive style. Owing to the great cost of lumber,

this article had to be economized to the utmost, the crystallizing vats and other portions of the plant being left uncovered, as shown in the cut illustrating one of these es-

PIONEER BORAX WORKS ON THE DESERT.

BORAX MINE.

INTERIOR OF THE MINE.

establishments. But in the hot and desiccated atmosphere that for two-thirds of the year prevails in that region, this was no detriment so long as the workmen could be

The Thompson Engine.

On another page is the description of the new Thompson engine built in this city by the Golden State and Miners' Iron Works for the World's Fair. A cut of the single cylinder engine of this improved type is given on this page. The Ferries and Cliff Cable R. R. Co. of this city is running its whole system with one of these engines. These are single cylinders, 24x48. The Los Angeles Electric Railway Co., the most complete plant in the State, has two sets of triple-expansion engines of this type. The cylinders are 16 and 22 by 32, and as high as 800-horse power is developed. The Pacific Rolling Mills of this city runs its machinery department with an 18 and 32 by 42 tandem compound engine of this make. The Oakland Gas, Light and Heat Co. has a 24x42 single cylinder engine for its dynamos. The Fresno Gas and Electric Co. at Fresno has a tandem 16 and 28 by 30 Thompson engine. The Norton Tanning Co. has the original Thompson engine—the first one built—a 14x30, which, after years of use, is so well liked that it would not take any other as a gift. The Mendocino Lumber Co. has the second one built, and sent recently a most flattering testimonial of its continued efficiency. The engines are made any desired size. They have been made as small as 8 and 14 by 24 tandem compound, and from that up to the sizes mentioned. The Golden State and Miners' Iron Works refer confidently to the owners of any of these engines as to their complete success.

CITY AND COUNTY ATTORNEY CRESSWELL has rendered the Board of Supervisors an opinion that the Board is entitled by law to fix rates for individuals or corporations furnishing light generated by electricity to the residents and householders of the city of San Francisco.

Mr. Cresswell holds that Section 19 of Article 11 of the State Constitution, which refers to "artificial light" and "illuminating light," embraces, by proper interpretation, light generated by electricity, and that inasmuch as the Constitution does not require the Legislature to pass laws in aid of the

I. F. THOMPSON'S SLIDE-VALVE CORLISS ENGINE.

protected in part, at least, from the rays of the sun, which here strike down with a killing heat the whole day long.

section in question, but confers the power of regulating charges upon the municipal government, the power of the Board of Supervisors is ample and unquestioned.

CHAS. G. YALE, EDITOR

Our latest forms go to press on Thursday evening.

Entered at the S. F. Postoffice as Second-Class Mail Matter.

San Francisco, March 4, 1893.

TABLE OF CONTENTS.

ILLUSTRATIONS—Pioneer Borax Works on the Desert; Borax Mine; Interior of the Mine; I. F. Thompson's Slide-Valve Corliss Engine, 129.
EDITORIALS—An Abnormal Borax Deposit; The Thompson Engine, 129. Comment: The Caminetti Hydraulic Mining Bill a Law, 130.
CORRESPONDENCE—Gold and Silver Mines and Mineral Lands in 1893, 133. Some Points in Silver Milling by Amalgamation, 133.
MISCELLANEOUS—American Miners in British Columbia; Going to South America, 133. The University Laboratory of Entomology and Plant Diseases; Bezoar Stones; Mint Director's Report, 134. Foundry Notes, 131. Coast Industrial Notes, 132. Mining Briefs; The Late Henry Martin, 133.
MECHANICAL PROGRESS—Gas-Saving Appliances; Shop Suggestions; A Cotton Belt; Mannesmann Locomotive Boiler Tubes; Fine Mechanical Work, 136.
SCIENTIFIC PROGRESS—Chemistry of Storage Batteries; The Wetting of Coal, 136.
ELECTRICITY—Electricity and Disease; Electricity on Canals; How It Is Done; The Conductivity of Insulating Bodies, 133.
USEFUL INFORMATION—Yellow Pine and California Building Lumber; Cost of Furs; "Heart Failure" and Stomach Stuffing, 133.
MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific States and Territories, 125, 126.
MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings; Assessments, Dividends, etc., 127.

Comment.

What is usually called the "desert regions" of this State in portions of San Bernardino, Inyo and San Diego counties, doubtless contains much wealth in its mineral deposits. A few years since we published in the MINING AND SCIENTIFIC PRESS a series of letters written by James H. Crossman, on the mineral resources of San Bernardino county, in which attention was called to many good prospects in the desert regions of that county. These were undeveloped mine, but the indications all pointed to a possible future for the section if capital would help the prospectors out. The fact that some of the successful Nevada silver miners have gone to work in Vanderbilt district on the Mojave desert, will soon attract attention to that part of the State, and other men will begin to invest. There is a large area only partly prospected in the counties mentioned, and although there have been many legends of rich mines, few have been opened. The New York district, on the Mojave desert in San Bernardino, is another district which is beginning to be noticed. They have found ore running from \$40 to \$68 per ton, and the bullion contains a liberal proportion of gold. The mountain ranges bordering the desert have been visited by very few expert prospectors or miners and a thorough search may result in the formation of several new districts.

Mr. J. J. Crawford, of Placerville, took his position as State Mineralogist this week in place of Wm. Irelan Jr., whose term expired March 1st. At first Mr. Irelan contended that he was entitled to one year more in his official position and declined to give way to Mr. Crawford, but better judgment prevailed and he sent word to the Governor by Mr. Davis, one of the Mining Bureau Trustees, that he was willing to vacate at once. A legal complication, such as was at one time threatened, would, without doubt, have jeopardized the appropriation for the Bureau, since it was "in the air" that there must be a change in the management if the Bureau was to go on and be properly supported. The bill defining the duties of the State Mineralogist and describing the method of conducting the Bureau has been favorably reported by the committees of both Houses, but has not yet passed. There is also a bill appropriating \$75,000 for the support of the Bureau, and this is still pending. Mr. Crawford, the new Mineralogist, is a gentleman of experience and ability, who will endeavor to make the Bureau of as much practical use as possible to the miners of the State.

Judge Hallett, of the U. S. District Court, at Denver, Colorado, has very sensibly decided that any stockholder in a mining corporation has a right to enter the mine and make an examination of the property to his own satisfaction. The decision was made in connection with the suit of Capt. Thatcher against the Mollie Gibson

Mining Company of Aspen. The Mollie Gibson has, during the last 12 months, paid dividends amounting to \$1,800,000, and the January dividend has been declared this year; but while this is the case, stockholders have been compelled to blindly await results, as the managers refused admittance to any but the officers of the company, while workmen in the mine were sworn to absolute secrecy. It seems absurd that a stockholder, who is of course a part owner, should be kept out of the mine by the managers; yet the managers, that is the directors, often keep all the information to themselves. It is frequently the case that these directors, after election, only hold just enough stock to keep their seats, selling the balance. They can then wreck a company if they chose, with no chance of financial loss to themselves, while the bona-fide owners of the mine—the stockholders—have not a word to say. This has been so common a custom here that it has nearly killed the mining-stock market on this coast. Judge Hallett's decision is not only good law, but good sense—something which cannot always be said of judicial determinations. Stockholders in all mines should be permitted to see their property when they want to and know everything that an owner should about it. They have pending before the Colorado legislature a bill making it obligatory on the mining companies operating in the State to set apart two days out of each month when stockholders may visit the properties in which they are interested. The bill provides that this shall be done when a person or persons representing one per cent of the capital stock of any company shall apply for admission on the days so set apart. This gives the minority stockholders an opportunity to inspect the property in which they have an interest, and relieves the management of a property of the inconvenience caused by interruption at all times, except upon the two specified days.

There is a strong organized opposition to Senator Ford's bill legalizing hydraulic mining in this State, the Anti-Debris Association and Sacramento Trustees both having passed resolutions against it. This bill has already been reported favorably by the Mining Committees of the Senate and Assembly and passed the Senate. It will probably pass the Assembly also, despite the opposition. Only one man in the Senate voted against it. The bill permits any one to mine by any process wherever the same can be done without material injury to navigable streams or adjacent lands. The word "material" is what has mainly aroused the antagonism, though on general principles the Anti-Debris Association objects to anything which looks favorable to the miners. This bill only puts in the code what the courts have already decided to be legal.

Since the above paragraph was written, we received a dispatch on Thursday that this bill passed the Assembly by a vote of 50 to 20. It has already passed the Senate and will be signed by the Governor without doubt.

It is probable that Mr. Ford's bill to create a State Debris Commission, consisting of one man, to co-operate with the Government Commission, will pass. It has already passed the Senate by a vote of 30 to 5. The Caminetti bill having become a law, and provision having been made for consultation with a State Commission, Mr. Ford's measure should pass also. It does not become operative unless an appropriation is made by the Government for debris dams, and this is something for the future.

The Caminetti Hydraulic Mining Bill a Law.

The President of the United States has signed the Caminetti bill, and it is now a law. We have been hoping for some months to be able to write that sentence, since it legalizes hydraulic mining in California under certain specified conditions, and brings to an end a struggle which has gone on many years.

After the bill had passed both houses of Congress, it went to the President, and he referred it to the War Department for an examination, where it was held several days. Meantime, some officious clerk or subordinate had written an adverse opinion, because of the amount of unpaid work it might put upon the engineers of the Board of Commissioners. The bill, with these comments pinned upon it, reached the Secretary's desk just after Mr. Elkins had come in, followed by Mr. Caminetti. The latter explained the merits of the bill, and General Casey, coming in just at that time, admitted that, although he had never taken action upon it in his official capacity, he had individually approved it. Secretary Elkins remembered he had approved the bill himself last summer, and he accordingly ordered the clerk who had brought in the first report on the bill to take it back and write a favorable one, which was done. It was then sent to the President, who, on receiving the joint resolution passed by the California Legislature asking him to sign the bill, did so at once, and it became a law on Wednesday.

The fact is that the delegates of the State Miners' As-

sociation, when in Washington last year, had several conversations with General Casey and Secretary Elkins about this bill and some few changes were made at General Casey's suggestion, so they knew all about it and were favorably inclined, though General Casey knew it would add work to the members of the Engineer Corps who are to form the Commission. The Miners' Association delegates knew that this must be the case, and were therefore careful to consult General Casey a long time since.

We have published this bill in full twice, and commented on its various sections so frequently that the general features are familiar to our readers. The miners who desire to mine by hydraulic process must apply to the Government Commission for a license, and this is granted when the miner shows to the satisfaction of the Commission that he can impound the debris and keep it out of the navigable rivers. This is the main feature of the law.

It must be confessed that the new law is not entirely satisfactory to all the miners, or to the valley farmers either. The latter generally do not want to see any dams or any hydraulic mining. Some of the richer miners think they can get on without a law, under the recent court decisions. The general consensus of opinion, however, is in favor of the new law as legally settling a long-contested dispute. The miners will no longer have to deal with spies, with prejudiced judges or inimical anti-debris associations, but with an independent commission of engineers, free from political surroundings, unbiased and technically skilled in engineering propositions such as this is. The anti-debris spies will be out of a job, and the association will have no further "say." There will be no more levying of blackmail for illegal mining on the part of anybody. This law finishes that flourishing business, and the miners who break the law will be punished, as they should be.

So, altogether, though the original measure has been changed, even in its modified form it might have been worse for the miner than it is. Mr. Caminetti has worked hard and deserves credit for his exertions. It is but fair to say, however, that without the strong backing and efficient aid of the Miners' Association of California he could not have accomplished the passage of his bill. This is evident to those who know the facts of the long struggle.

Foundry Notes.

At the Golden State and Miners' Iron Works this week they completed ready for shipment a very handsome 300 horse-power compound engine which is destined to run one of the six lines of shafting in the Machinery Building at the World's Fair. It is the I. F. Thompson automatic, independent, cut-off, slide-valve type, and is entirely of California design and manufacture. The engine is handsomely decorated. The lagging on the cylinders is of California laurel, banded with oxidized copper. The machine work is bright while the castings are painted and gilded in a tasty manner. This type of engine has been very successful where introduced, and several of quite large size have been built.

In the Thompson form of construction, the valve rod is continued from the eccentric through the exhaust chambers, in each of which is a slide-valve attached to the rod and moved regularly by the motion of the eccentric. In each end of that portion of the steam chamber above the exhaust chambers is a separate slide-valve suited each to its steam port, and from each valve a rod or piston passes out through the end of the steam chest, carrying a trigger with steel face, and on the end a dash-pot to resist the momentum when the valve and rod are thrown.

Upon the exhaust valve rod, at each end of cylinders, is an arm with steel face, which, coming in contact alternately with the trigger upon valve piston at each end, moves the valve off the steam port, and the steam being brought down to the steam port in undiminished volume and power, just enough enters the cylinder, which in its initial and expansive force is sufficient to do the work required for that portion of the stroke, when the wedge moved by the governor raises the trigger out of contact with the arm on the exhaust valve rod, and the steam valve is constantly closed by the pressure of steam upon the valve rod or piston within the steam chamber.

The wedge being set so as to trip the trigger when the engine is running at normal speed, under normal steam pressure and with a normal load, every change of load or of steam pressure in the boiler is instantly followed by a change of the position of the wedge backward or forward as the load or pressure is increased or diminished. For instance: Suppose the normal conditions are 80 pounds pressure of steam, 100 revolutions and the cut-off at one-fifth stroke. Now there comes an added load or the pressure of the steam is decreased. Instantly the governor feels the change, draws the wedge back, allowing the valve to move that much farther off the port and more steam to enter. Again the load decreases or the steam raises, the governor instantly moves the wedge forward and closes the steam port that much earlier.

The governor for these engines is of a new and peculiar design and very simple. It consists of an arrangement of centrifugally-acting weights, the arms of which are so connected with the driver and parts to be driven that the connecting arms form toggle or knee levers. The angle at the junction of these knees is most acute when the governor is in a state of rest, and it becomes more obtuse with a corresponding increase of the knee power as the weights separate. In conjunction with the arms and weights is a spring so connected that its tension increases as the centri-

fugal force throws the weights outward, but as the power of the knees also increases, the two serve as a counter-balance for each other, and the governor thus becomes differential in its action.

All eight valves are moved by one eccentric, and but one joint between the eccentric and valves.

Engines of this build are running with the most uniform motion under the most sudden changes of load, and with remarkable economy of steam, of sizes—12 in. bore, 24 in. stroke; 14 in. bore, 30 in. stroke; 16 in. bore, 30 in. stroke; 24 in. bore, 42 in. stroke; 28 in. bore, 48 in. stroke; 10 and 17 in. bore, 24 in. stroke, compound; 12 and 20 in. bore, 30 in. stroke, compound.

Its superiority over the Corliss style, the most approved heretofore, consists in—1st. Simplicity of parts, in having but one joint between the eccentric and the valves, against six in the most simple, and as high as 25 in other styles of the Corliss as now made, so that any intelligent engineer can run it. 2d. Plain, flat slide-valves and seats, instead of rotary or circular. 3rd. Sharper cut-off, insuring greater economy of steam. 4th. It can be run up to 200 revolutions per minute, against a possible 100 revolutions of the Corliss.

On the first page is an engraving of this form of engine, with some account of where it is in use on this coast.

THE Risdon Iron Works report quite a little "boom" in Bryan quartz mills, which are meeting with great favor among the miners. A contract which all the Colorado foundrymen were after came to this city because the Bryan mill was preferred for the plant by ex-Senator Tabor. This is a 60-ton free milling silver pan amalgamation plant on the tank system, consisting of four 4 foot sectional Bryan mills with eight 5-foot pans and four 8-foot settlers, with a 12 and 22 by 34 compound Myers cut-off engine, and 50x60 boilers. The whole machinery for the complete plant is made in sections for mule-back transportation. It is being built by the Risdon Works for Hon. H. A. W. Tabor of Denver, for the Tabor Mines and Mill Co., and will go to Santa Ednevijs, in Jesus Maria district, State of Chihuahua, Mexico. The outfit is a very complete one of the best design and workmanship.

The Risdon Works are also building about a dozen Bryan mills 5-foot solid, 4-foot solid and 4-foot sectional. These mills are giving satisfaction and there is an increased demand for them by miners. They have also in view a plant consisting of seven 4-foot sectional Bryan mills, with the necessary concentrators, etc., for gold ores.

THE Congressional appropriation bill this year has a provision which gives this coast a better chance in the future for building Government vessels. After authorizing the construction of four 1200-ton gunboats, the bill provides "that, in awarding the contract for any one of these ships, the Secretary of the Navy shall award the contract, at the price of the lowest bid, to that one of the parties bidding on any such ship which in his judgment it is in the interest of the Government to have to do the work." This will enable the Secretary to have one or more ships constructed on the Pacific coast, even if the first bids are not the lowest.

THE new water works at Golden Gate Park will be ready for use about the first of May. The old pumps, even when in constant operation, can supply but 250,000 gallons, while the new pumps can furnish a minimum of 1,350,000 gallons per day, and, when driven to their full capacity, can furnish 2,000,000 gallons. Enough water is thus provided for every requirement of the park when the improved part of its area is extended as far west as Strawberry hill. The water supply of the park is derived from eight artesian wells, the majority being 20 inches in diameter and 120 feet in depth. One of these wells is no less than 5½ feet in diameter and 130 feet deep, into which an extension has been sunk 90 feet deep and 20 inches in diameter. Of these wells, five are new and three are those from which the present supply is derived. They will furnish more than the quantity that will be required, and the quality is said to be extraordinarily good. The pumping engines, built by the Union Iron Works, are fine pieces of machinery. There are two independent sets of pumping engines of the horizontal compound type, the pumps being driven direct and attached to the back ends of the piston-rods. The high-pressure cylinders are 12 inches in diameter, and the low-pressure are 20 inches in diameter, 24-inch stroke. The pumps are of the double plunger type, 5½ inches in diameter and 24-inch stroke. The valve-seats are made of phosphor bronze, with hard rubber valves incased in a cast iron body with side doors, so that the valves can be easily examined and repairs expedited. The air chambers on the suction pipes are 12 inches in diameter and six feet six inches high, and the discharge pipes are also 12 inches in diameter and eight feet high. Each set of pumps has its own air pumps and condenser worked from the cross-head of the main engines. These are vertical, of cast iron and lined with phosphor bronze. The main engine frames are of cast iron of the Corliss type, with adjustable bearings. The pumps and engines are securely tied together by a bed-plate running the entire length of both.

The boilers are two in number, 54 inches in diameter and 16 feet long, and are known as the "elephant" type, to work under a pressure of 100 pounds per square inch. Each boiler will have two water-drums, 27 inches in diameter and 21 feet long, and a steam-drum, 30 inches in diameter and 10 feet long.

THE "Legislative Excursion" to Grasa Valley and Nevada city took place last Sunday, when about 200 persons, including members and attaches of the Legislature, went from Sacramento under the guidance of Assemblyman Thomas and Senator Ford. The visitors were hospitably received and were given an opportunity to visit the principal mines.

SEVERAL of the assistants in the State Mining Bureau were relieved from duty by Mr. Irelan before he relinquished his office. Among them were Messrs. Fairbanks, Storms and Preston.

Coast Industrial Notes.

A MUTUAL AID ASSOCIATION of telegraph and telephone men has been organized in this city.

It is considered a settled fact that an electric railway will be built from Sutter Creek to Ione, Amador county.

THOS. DIXON, of Eureka, Nev., has secured the lease of several rich dumps in Inyo county, Cal., for jiggling purposes.

THE steamer St. Paul, chartered by the North American Navigation Company from the Alaska Commercial Company to run on its new line established between here and Panama, will leave here on the 9th inst.

THE completion and operation of the smelter and reduction works now building in Los Angeles will do much to expedite the building of a railroad to Owens valley, and thus make the rich mineral belts of Inyo tributary to the enterprise of Southern California.

THE Great Salt Lake Railroad project is dead. All its employees, including Chief Engineer Kennedy and his corps of engineers, have been paid off and discharged. The opposition of the Traffic Association to the Consolidation bill is the cause of this action.

THE Oakland Council and Board of Public Works will compel all electric roads in that city to at once put up guard wires alongside its trolley wire. The only roads now using the guards are the new Telegraph avenue line to Berkeley, and the Haywards line.

THE new jetty at the entrance of San Diego harbor will be commenced at once. The plans have been prepared, and Colonel W. H. H. Benyard of the Engineering Corps of the army, will at once advertise for bids for the work. The cost will approximate \$500,000.

ARTICLES of incorporation of the Wentworth Boot and Shoe Company have been filed with the Sonoma county clerk. The capital stock is \$200,000, of which about \$40,000 have been subscribed by Santa Rosa capitalists. The concern was formerly operated in Oakland.

THE new 30-ton gasoline schooner Jessie Madsen, designed for the trade between Bolinas bay and this port, was launched from the ways at the foot of Taylor street at North Beach on Tuesday. The new schooner will replace the old Espinosa, which has been on the run many years.

J. H. HENRY, a capitalist, has made a proposition to the Sacramento City Trustees to erect a plant just east of the city, and supply the municipality with pure water from artesian wells sunk in the gravel-bed section, for 15 years, at the same cost as the city is now at for pumping from the river.

THE work of shipping the exhibits from the Pavilion to the World's Fair is about completed, and all that now remains is the private displays throughout the State, which will soon be forwarded, as before the 10th prox. all exhibits must be placed in the various departments of the State buildings.

A SYNDICATE of Chicago capitalists has been formed to supply water to the small towns along the line of the San Francisco and North Pacific from Healdsburg south to Tiburon, including the towns on the Guerneville and Sebastopol branches. The necessary water is to be obtained from the Russian river.

THE great pumping plant which will supply Yuma and Yuma Heights with water, and which will irrigate 10,000 acres of land on the high mesa near the town, started up on February 27th. It raises the water 80 feet and forces it through a 26-inch pipe three miles. The project marks a new era in irrigation, as it shows that the high mesa lands, worthless without water, can be reclaimed wherever water can be had for pumping. It also marks a new era in Yuma's prosperity.

THE Southern Pacific Company has ordered eight switch engines, 14 compound passenger engines and three compound freight engines. Those for the passenger service have ten drive wheels, and will be put upon the mountain divisions. But the freight compounds will be about the biggest engines that have ever been built. They have 12 drive wheels and weigh 55 tons on the drivers, while the total weight of the engines will be 135,000 pounds. The company will also build 500 freight cars at Sacramento this season.

A. W. JONES of Kansas, who is back of the Fresno and Monterey road, reports the enterprise moving forward with gratifying expedition. Monterey has collected all and San Benito nearly all of the required bonus, while the former's water frontage and a city franchise has been granted for 50 years. The right of way through these counties has been secured except that for entering Salinas, the granting of which there is no doubt. The chief engineer reports a grade not exceeding 80 feet to the mile through the mountains. Meantime, the local committee, securing Fresno's \$75,000 bonus, will visit Malaga, Friday and Saturday, in furtherance of the matter. Some \$40,000 has already been secured.

DUDLEY H. HERSEY, a wealthy lumberman and capitalist of St. Paul, who has been making a tour of the Pacific Coast with his wife, being asked about the purchase of timber lands in Oregon and Washington by Minnesota and Wisconsin lumbermen, said: "The timber purchased will not be cut at once. There is plenty of timber in Wisconsin and Minnesota, and the lumbermen have bought lands on the Pacific Coast so as to have a reserve in case of necessity and to supply local demand. Lumber could not be placed on the Eastern market and net shippers a profit under existing railroad rates, but in course of time, when there are more railroads built in the country and competition is active, the business could probably be put on a paying basis."

THE whaling steamer Jeanette was launched at Turner's shipyard, Benicia, on Saturday last. The Jeanette is the first atom whaler built on the Pacific coast. She is a very fine model, both for steaming and sailing purposes, and is very satisfactory to her owners, Messrs. Roth, Blum & Co.

of this city. The Jeanette, which is 350 tons, will be commanded by Captain E. W. Newth, formerly of the whaling schooner Alton, which has made so many successful voyages in the Arctic ocean. She will be ready for sea about March 25th, and has engaged some of the best whalers. She is to be fitted out with the very latest improvements in machinery and for the comfort of the officers and crew.

REGARDING the statement published to the effect that the Southern Pacific Company has just set to work a force of 1000 men in that section of country between Santa Margarita and Ellwood, Chief Engineer Hood says: "The fact is that we have not got 1000 men at work as reported, but only about 600, and these have been at work all winter. They are laying the new coast division that is to run between the places mentioned. Some time along in the spring we intend to increase the present force, but to what extent I can't say yet. As to when this division will be in operation, that I can't say either, but it will not be any time this year."

AN ORDINANCE was presented at the last meeting of the Santa Rosa City Council declaring that the public necessities demand a system of water works for the city. The question of Santa Rosa constructing and owning its water system has been under discussion for nearly two years. The action taken on Saturday is the preliminary step which will result in a proposition to issue bonds and construct water works being submitted to the voters at an early date. The city officers recently visited Santa Cruz and other cities that own their water works, and it is probable that an election will soon be called to decide the issue. If the proposition be carried a pumping system will probably be built.

J. A. LIGHTHOPE, District Engineer of the General Electric Company, read an interesting paper on "The Incandescent Lamp" before the California Electrical Society Monday night. Mr. Lighthope, who was employed in Edison's Laboratory for some years, gave an account of the many experiments made before the platinum filament was superseded by the carbonized bamboo now used in the manufacture of lamps. A general discussion on electrical improvements followed. The society has elected the following officers for the year: President, George P. Lowe; vice-president, O. C. Poole; treasurer, H. G. Bator; secretary, G. Max Caspari; executive committee—E. A. Roe, O. Brooks and B. Elder.

EX-SENATOR JAMES G. FAIR, in speaking before the supervisors' committee on establishing grades near Lobos square, explained that he proposed to make vast improvements in the neighborhood of Lombard and Bay streets, and that, as soon as the board had settled the grades, he would employ about 200 men in doing the necessary work. He said that he owned about 50 blocks of land, a considerable portion of which was under water. As soon as the grades of the streets on the beach property, from Van Ness avenue to the Presidio line, had been established, he intended to fill in the water lots and construct a concrete seawall. He considers that that neighborhood was destined to be the principal manufacturing district of the city, and he intended to invest considerable capital there in improvements.

A. M. CANNON JR., of the *Deseret News*, Salt Lake, says it has been generally dull throughout Utah for some time. In Ogden it has been unusually so, and it has been quiet in Salt Lake, but he thinks times will begin to improve soon. The past dullness has been to some extent produced by overgrowth, and it has required a little time to catch up. Now new enterprises are beginning to start again in different parts of the Territory, and the quiet period promises to end. "Salt Lake is so important a city and is such a natural business center for a vast region," said Mr. Cannon, "that it cannot remain inactive long. The spring that is just opening indicates that there will be a new impetus in nearly all lines of business, and besides this, there will be increased development of the mining, agricultural and other resources."

CAPTAIN JOHNSON, of the big three-masted schooner Beulah, brought his vessel from Redondo to San Francisco without a man in the fore-castle. The Beulah took 415,000 feet of lumber to Redondo from the north coast, and while discharging the walking delegate of the Sailors' Union captured her crew. Captain Johnson tried in vain to ship a fresh crew of non-union men, and when a crew went down from here was also captured he swore that he would never allow a union sailor to step foot on the Beulah's deck if she had to rot at her anchorage. It looked as though the schooner would rot for a time, but on the 18th Captain Johnson, tired of inactivity, sailed, with only himself, two mates and the cook to work ship. The donkey engine was used to hoist sails and the simplicity of the fore-and-aft rig enabled the four men to bring the big vessel to port safely.

HENRY C. MYERS, of Klamath county, Oregon, which lies immediately north of Siskiyou and Modoc, in California, and has Klamath Falls for its principal city, says there is now much interest in Klamath county, by reason of the construction of a new railroad from Castle Crag, on the California & Oregon road, to Klamath Falls. "The road is to be built by D. E. Miles, formerly of Chippeway Falls, Wis., and associates," said Mr. Myers. Mr. Miles is one of the head men of the Red Cross Lumber Company, and is president of the new railway organization. It is called the Northeastern California Railroad Company. The line of the new road has already been determined on as far as Bartel's, in Squaw valley, Shasta county, a distance of 30 miles, but it is stated that the rest of the road will be surveyed and run through as fast as it can be done.

MAX PRACHT, Special United States Agent for the protection of the salmon fisheries of Alaska, and lately instructed to utilize the island of Afognak as a salmon reserve, has finished his work in Washington, where he has been for some time, and is once more on the coast. Special Agent Pracht says that late figures collected by him show that the entire pack of salmon for the district of Alaska for the year just closed consists of 457,969 cases,

15,252 barrels and 4,245 half-barrels of salted whole salmon. Besides these there were 35 barrels and 36 half-barrels of salted salmon bellies. He gives the money value in San Francisco of the salmon, other fish and fish oil of Alaska for 1892 as follows.

Salmon.....	\$2,064.340 05
Codfish.....	104,062 00
Salted herring, herring oil and guano.....	86,537 50
Dogfish oil.....	3,000 00

Total.....\$2,257,939 55

The largest contract job on the water front for many years will be that for the foundation of the new ferry building. The bids opened last week, ran from \$328,500 to \$545,000, but none were accepted by the Harbor Commission as the plans are to be modified. While the board does not desire to cut the building in size, the members have suggestions for a modification of the foundation which will materially reduce the cost, and if they do not they will permit of construction by sections in such a manner that the whole can be finished about as planned as the fund for the purpose grows. In the new idea caissons to take in the full length of a row of foundation piers instead of a coffer dam for each pier, will effect an immense saving, and the plan of procedure will be worked out in a few days. A fact not generally understood is that the \$600,000 to be raised by the bond issue will be entirely required for the building proper, and the foundation, which is a work of about two-thirds the expense of the structure, must be paid for out of the harbor fund.

IRLAND & VICEY, contractors of Los Angeles, have secured the contract for constructing the canals and reservoirs to be built 60 miles east of Yuma, on the Gila river, Arizona, by the South Gila Canal Company. The engineering work has just been completed by Chief Engineer B. S. Church, of the New York water works, who built the celebrated Croton aqueduct. The canal system will cost about \$2,000,000, and will irrigate about 300,000 acres. It may be extended to include 1,000,000, and will bring an immense amount of arid land under cultivation and do much toward furthering Arizona's progress. Mr. Ireland says that the contract awarded to his firm includes about \$2,000,000 worth of work. There are 72 miles of canals and reservoirs to be built. The dam will be one of the largest in the country and will be made mostly of asphalt, some cement being used. It will be 1400 feet long, with a height above the water level of 32 feet and a depth below the water level of about 30 feet. The full force of men employed will be about 500, and it is thought the work will be completed in about a year and a half.

Mining Briefs.

THE loss of the Daly Co., Utah, through decrease in price of silver since 1891 is \$118,000.

PINOS ALTOS, N. M., has 75 stamps dropping on gold ore from the mines of that district.

CREEDE's ore shipments for January, '92, amounted to \$105,500; for January, '93, \$90,000.

THE Henry Mountains, Utah, are running opposition to the San Juan fields in the matter of new placers.

THE machinery agents say that the demand for mining machinery is very light at present in all the mining districts of the country.

THE miners of Silver City, N. M., held a meeting on March 1st to make arrangements for the Southwest Silver Convention, to be held at that place on July 4th.

THINGS are looking rather blue at Rich Gulch, Chisleva Co. The mill at the Quartz Glen Mine has been shut down and several men discharged. It is rumored that they will sink a new shaft in the near future.

SENATOR FORD has a bill appropriating \$500 for editing the manuscript of the report of the State Mineralogist for two years, ending Sept. 15th, 1892. This is the report of which the Governor spoke in his message as being too voluminous, and requiring better editing.

THE Supreme Court has accepted the new bond in the Hale & Norcross suit. The sureties are: Alice M. Hobart, \$1,000,000; Ella V. Hobart, \$1,000,000; C. O. Lane, \$300,000; Charity Hayward, \$600,000; W. J. Dingee, \$600,000. It will be noticed that the five persons qualified for over \$4,000,000, although the bond called for but \$2,030,000.

JAMES L. GOULD, the well-known miner of Gold Run, Placer county, has been cited to appear in Superior Court at Marysville, April 10th, to show cause why he should not be punished for contempt for violating an injunction prohibiting him from mining by the hydraulic process. Several other miners at Gold Run have also been cited.

WM. YANEY writes from Holtrock, A. T., about the San Juan country, saying that while there is a little gold all over the country, when they reach bedrock they find more. He thinks the excitement was arranged by certain storekeepers to make money out of the public. He says the gold dust reported to have come from the San Juan, was purchased elsewhere.

At a miners' meeting held in Antelope gulch in the lower end of the Little Hatched mountains, N. M., on the 14th day of February, 1893, the following mining district was formed, said district to include all the Little Hatched mountains from Howell's ranch to Rector's ranch: "Wines' Mining District, Grant Co., New Mexico." The recorder of the county is the recorder of the district.

MR. JOHN MACKAY, the bonanza millionaire who was shot by a crank mining-stock dealer named Rippey, is rapidly recovering. His assailant, who also shot himself, is in a precarious condition and not expected to live. Rippey had been dealing in stocks and losing money, for which he held Mr. Mackay responsible. Mr. Mackay did not know the man, and had never had any dealings with him.

THE last of the "lost mines" re-found is in San Luis Obispo county, four miles northwest of Beaus, which place

is near the first of the new tunnels of the S. P. R. R. Co. The usual accompaniments of old dump, old tunnel and abandoned arrastre, are announced. Moreover, there is an old Spanish mission mixed up with the legend. It is that of San Miguel, when they were supposed to have lots of silver from this mine.

THE *Park Record* (Utah) says that Joseph Frates, an old Daly miner, returned from a lengthy sojourn in Butte City, Anaconda and the Wool River country, and when told by one of his friends that it was very dull in the Park he exclaimed: "Dull! Why, man, it is lively here compared to the country I came from. The whole country is dead up there; absolutely dead. There is nothing doing and the miners cannot make a living."

By a recent decision of the attorney-general of the Transvaal, the MacArthur-Forrest Company was restrained from claiming a monopoly of the cyanide process in South Africa, and it was held that no process in which cyanide is used in a different manner is an infringement on the MacArthur-Forrest patent. The decision is the outcome of an attempt by this company to restrain a syndicate from using the Mallory process, which differs from the former only in the matter of precipitation.

Some Points in Silver-Milling by Amalgamation.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by C. H. AARON.

When an alkaline ore containing a haloid salt of silver (chloride, bromide or iodide) is to be treated, surfaces of copper are much better than of iron, for the reason that they retain a coating of quicksilver; this applies to raw and roasted ores alike. The philosophy of the matter is this: If the silver is reduced to the metallic state in the absence of quicksilver, that is, out of contact with the mercury, it becomes so mixed with the muddy pulp, and possibly rendered insensitive to amalgamation by superficial chemical action, that its collection is extremely difficult—in some cases impossible. Hunting for a needle in a haystack is hardly more futile than chasing those infinitesimal particles of silver through tons of mud. On the other hand, if the silver is born, so to speak, in contact with quicksilver, it amalgamates in the act. Iron in an acid pulp, or copper in either an acid or alkaline menstruum, forms with mercury an electro-chemical couple in which the iron, or the copper, plays the positive role, and it is known that, in such a case, the positive element of the electrolyte tends toward the negative element of the couple; in this case, the silver salt is the electrolyte and the silver is its positive element. In an alkaline liquid, iron is far less positive than in an acid, and though it remains positive to silver, and perhaps to mercury also, yet, as these metals do not adhere to it, even though mercury may be present, a large proportion of the silver chloride must be metallized by the side or wings of the pan, the surface of the muller plate, etc., out of the immediate proximity of quicksilver and is thus liable to escape amalgamation.

I once had occasion to treat an ore in which the main part of the silver was in the form of pellets of chloride and chlorobromide in cavities of the gangue. The gangue contained a large proportion of calc spar and manganous oxide, which made the use of bluestone and salt impracticable; the manganous oxide also forbids the application of cuprous chloride. Certainly, these things were not necessary for the reduction of the silver to the metallic state, for which the iron pan was sufficient in the presence of salt; but the work was begun with pans that were well lined with coppery amalgam from the previous treatment of a roasted coppery ore, and it was observed that as soon as that lining had worn off, the tailings were richer than before, the bullion being quite fine. Experiment showed that it would require a barrel of sulphate of iron to a charge of ore to neutralize the pulp so that bluestone could "live" long enough to coat the iron with copper amalgam, which, in this case, would be the only object in using it. I therefore made cement copper from bluestone in a tub, and added a quantity of that to each charge of ore in the pans. The result was a slightly coppery bullion, but considerably better yield. Had it been possible to treat that ore with metallic copper in a wooden vessel, the extraction would have been still better, not as in the Aaron process, because of the reproduction of cuprous chloride, which would have been useless, but because all of the haloid silver would have been metallized in actual contact with quicksilver.

Although the copper chlorides, with salt, are the best agents, in general, for the treatment of raw ores of silver (even for metallic silver the cupric chloride is useful, because it produces a film of silver chloride on the particles, which dissolves in the salt pulp and is recovered by precipitation, leaving the surface of the particle sensitive to quicksilver), yet there are cases in which the copper chlorides are inapplicable, and other agents may be used to advantage. One such I have mentioned and I have now to write of another.

The ore contained a large proportion of zinc-blends and galena, also pyrites and calc spar, but about 75 or 80 per cent of the silver was in the metallic state. I made a number of experiments on the ore, on concentrates of two grades, and on tailings, in an experimental pan taking a charge of 200 pounds; very fair results were obtained, at a cost of 90 cents per ton, by the use of dilute nitric acid. In this method salt must be rigidly excluded, else the mercury will be badly granulated; even without salt I had, at first, some trouble with the quicksilver, but that was overcome by using sodium thiosulphate in the settler. The effect of the acid was to clean and sensitize the surfaces of the silver particles before it could be destroyed by the zinc-blende, etc. Nitric acid may sometimes be used with a quartz ore carrying a small percentage of pyrites.

Failure, as well as success, may be instructive; it at least teaches us what not to do, and, if its cause is ascertained, it may point the road to success.

I was once called on to work, without roasting, an ore

which I thought should be roasted. For reasons which I do not remember, I crushed rather coarsely, then ground in Wheeler pans with bluestone and salt, but not quicksilver, and tried to amalgamate in Wakelee pans. The result was a low grade of amalgam and little of it, in fact a failure. I explain this on the theory that the silver mineral was metallized in the first pan, and, being mixed with the pulp, could not be successfully collected by quicksilver in the other pan, the more so as that other pan was of the slow-moving class. This view is sustained by the fact that the next man who tried got better results by amalgamating, as well as grinding, in the first pan. His results, however, were not satisfactory. I did not fail to work that ore, for it was then that I discovered the Aaron process, which was not worked in pans. I bought some of the coarsely-crushed ore from the company, and, taking it to where I could treat it in a barrel, extracted a high percentage in very fine bullion.

In those days, it was considered necessary to grind in the pan; I had long before proved that grinding was not necessary for roasted ore, but had not applied the idea in raw working. The proper way to work that ore in pans would have been to crush it as finely as necessary by the stamps (or otherwise), and then work it in pans with bluestone and salt, keeping the muller raised just enough to avoid grinding, and with enough of quicksilver from the first to wet, so to speak, the silver at the instant of its birth (*in statu nascendi*).

The lesson to be drawn from the failure of my experiment is, to avoid reducing the silver to the metallic state in the entire absence of quicksilver; my successor's partial failure was due to the rapid decomposition of the copper chloride, formed by bluestone and salt, by the clean iron surface and the iron powder resulting from grinding.

It may be objected that the universal practice, whether in the Freiberg barrel or the pan, is, and always has been, to reserve the mercury until the pulp has been worked for some time in contact with iron. As a matter of fact, however, a barrel or pan that has been used always retains a quantity of quicksilver and amalgam, and a new pan or barrel should not be charged without some quicksilver.

The practice of reserving the quicksilver seems to be an heirloom from Freiberg. The Freiberg process was devised by a chemist, and his object in delaying the addition of quicksilver was, to allow time for the scrap iron to reduce the ferric and cupric salts in the roasted ore to ferrous and cuprous salts, which are innocuous to the mercury. The chemical action is much less rapid in the barrel than in the modern pan, and a period of two hours was not very dangerous even if no quicksilver at all had been present, especially as the pulp was not heated by steam but only gradually, by the chemical action. In fact, however, there can be but little, if any, ferric or cupric salt in roasted ore, and I doubt much if the whole of the required mercury might not just as well, or better, be added with the charge of ore in either barrel or pan. The older metallurgists sometimes provided against dangers which had no real existence. For instance, in the Plattner process we are directed to roast the ore "dead" because ferrous sulphate precipitates gold from its chloride, but experience has proved that dead roasting is neither necessary nor desirable, as the ore often works better without it, to say nothing of the saving of time and fuel which fully offsets the greater consumption of chlorine to convert the injurious ferrous salt to the harmless ferric.

Again, at Freiberg, it was considered indispensable (at least the books so state) that a silver ore for roasting should yield 30 per cent of iron, or mixed iron and copper matte in an assay for matte. Every smelter and millman will admit the desirability of having a uniform grade and quality of ore to work, and this advantage the Freiberg metallurgists were able to command by mixing different ores, and by rejecting any that were unfit for roasting, and sending them to the smelting department, etc. But in this country we have not had those advantages, and we have found that we can sometimes do very good work with ores that would have been condemned as quite unsuitable for the process which alone we could command. In other cases, we have done the best we could. Pupils naturally tend to follow the instructions of their teachers, and servile imitation without proper regard to conditions too often results.

The Late Henry Martin.

Henry Martin, one of the owners of the famous Brown Bear mine of Deadwood, Trinity county, died suddenly this week after an illness of only two days. His wife, to whom he was devotedly attached, has been seriously ill for some time, and her life is despaired of. She has not yet been told of her husband's death. Mr. Martin was a very popular man and made friends with all with whom he came in contact. Although made very wealthy by his ownership in the mine, he was always the same plain Henry Martin that he was in poorer days.

President Neff of the executive committee of the State Miners' Association called a special meeting of the committee on Tuesday to take action on Mr. Martin's death, and a committee, consisting of John Hays Hammond, Julian Sontag and Chas. G. Yale, was appointed to officially represent the association. The other members of the executive committee also attended. At the meeting the following resolutions were adopted:

Resolved, That in the death of Henry Martin, the miners of Trinity county, and indeed those of the whole State, have lost a steadfast friend, and one who was unselfishly interested in their welfare. A practical miner himself, his great financial success in his vocation brought no change in his demeanor or feelings toward his old associates, although it enabled him more freely to exercise that liberality and generosity which was always part of his nature. As a member of the Executive Committee of this association, his advice was most valuable, and he has frequently come to its assistance in a material way as occasion demanded. A member of the Association from its inception, he has never faltered in his zeal for the miners' cause or doubted the ultimate results to be accomplished.

Resolved, That a copy of these resolutions be forwarded to Mrs. Martin, to whom we extend our sincere sympathy for her great loss.

Gold and Silver Mines and Mineral Lands in 1893.

A Random Record of Private Opinion on the Situation.

SHADY RUN, Feb. 25, 1893.

TO THE EDITOR:—The *Examiner's* call for a motto or watchword for 1893 was responded to by many of the wise men of the State and nation, and their contributions published in the issue of Jan. 1, 1893. These embrace a wide range, including nearly every position, profession and calling from the President of the U. S. to a justice of the peace. In this great array of wise sayings there is one important omission in regard to a common business matter, upon which, to a great extent, everything else depends. I suggest that the MINING AND SCIENTIFIC PRESS supply this omission by adopting for a motto: "Our Gold and Silver Mines and Mineral Lands in 1893." ("Money is, in one sense, the most important tool used by man."—Senator Stanford.)

A man may own 500 acres of land, but if he has no money to stock and cultivate this it is worthless. A company may own 1000 miles of railroad with rolling stock, but if it has no money to purchase fuel and pay employees it is useless. The miners own rich mines; if they are prohibited from working them, where is the money to come from? The conflict in regard to hydraulic mining has been on for many years past. There has been much writing and a deal of talking for it by its friends, and fully as much or more by its enemies against it. This controversy culminated in a joint convention of the belligerents in San Francisco in January, 1892. In this "tug-of-war" the hydraulic miners had got to the end of the rope and were just holding on, and it seems they were willing to accept anything almost that gave any hope of success. The labors of the convention and the hard work of the delegates sent to Washington has brought forth the Caminetti bill, a compound measure of hydraulic mining, river improvement and valley protection. The friends of the bill concede that it is not just what the miners want, but is the best that could be done. The convention that met in November, being composed pretty much of the same delegates that attended the January convention, either had to indorse the Caminetti bill or admit that nothing had been accomplished.

The movement, which originated in this county something more than a year ago, spread like a cyclone through the mining counties. Subsequent events indicate that to some extent it was a spasmodic outburst from the surface; everybody was interested and excited for a short time. It had the semblance of the excitement following a discovery of new and rich diggings. The convention that met in San Francisco in January, 1892, was the largest body of representative mining men that ever assembled in the State. Every delegate knew just what the hydraulic miners wanted. How many of them had devised and formulated any method by which they could obtain just what they wanted? Very few, I think. It seems that a great portion of the delegates went there to see what the other delegates were going to do about it. The result is the Executive Committee and the MINING AND SCIENTIFIC PRESS have done about all of the earnest, effective work. It is doubtful if the spasmodic efforts of convention under these conditions will ever accomplish the desired result. "Be sure you're right and then go ahead." The great difficulty is in coming to an amicable agreement in regard to what is the right start, as the success of everything depends on starting in right.

There has never been a time in the history of mining in California that required as great a degree of intelligence, energy and harmony on the part of the miners as the present. The agitation now on affords them a favorable opportunity to make themselves heard and felt, instead of, as at present, a race of go-as-you-please, every fellow for himself and the devil for the whole batch. Have a thorough organization, as the workers in all other industries have. Organize a central association in each county, with branches in every mining town throughout the county where ten or more live, energetic, "honest miners" can be found to take hold and work in earnest. The central association should meet once or twice a year to summarize the work of the branches. The branch organizations should be required to meet regularly, at least once a month, for the purpose of exchanging views, discussing all matters pertaining to their interest, suggest methods, relate experiences and make their business a practical study. Thus organized on bedrock principles of right and justice, and conducted on lines of harmony and unity of action, definite and reliable information could be obtained in regard to the mines and mineral lands, more liberal and broad-minded views embraced, local fads, extravagant ideas and absurd theories eliminated, and the dishonest practices of mining sharps who dig up railroad titles to oust prospectors from the mineral lands, and the moonshine hydraulickers, controlled. The recent spasmodic flights taken by the miners' associations, not knowing where they will light, will never accomplish what the miners want. Special mining bills passed by Congress will help their cause but little. They must organize, demand and work for what they want.

I think the best and only means to remedy all of the difficulties will be to establish a Department of Mines, through and by which the miners can bring their wants and grievances directly to the attention of the head of the Government and secure the necessary appropriations, without any aid and hard work from members of the lower House.

The gold and silver mines already discovered and developed, and the vast extent of mineral lands where new discoveries are being made every year, unmistakably demand that a Department at the head of the Government should be created, having exclusive control and management of this great and indispensable branch of industry. It is to be regretted that all the labor and energy expended on the hydraulic bill was not devoted to this purpose. There seems to be a growing tendency for the Government to go into a general "commission" business. Commissions are

now appointed for almost everything, with discretionary power to run different branches of the Government. Their rulings are the law and they construe and, being intrusted with the power, enforce them, thus centering in one irresponsible body, it might be said, the three separate and regularly constituted departments—the legislative, judicial and executive, besides the extra expense incurred and not being accountable for any mismanagement.

A Department of Mines established, with an executive officer at the head, he could appoint his assistants and agents to control and manage all of the details of the Department, without the objectionable "commission." The first and most important work the Department should undertake would be to reconstruct the mining laws, instead of intrusting the matter to lawyers and Congressmen who know nothing about the mines or the miners' wants. The secretary of the Department should request a body of experienced and able miners, selected from the different classes of quartz, drift and hydraulic miners, to dig up some of the old district mining laws and modify them to suit the present conditions, so that he could recommend their adoption by Congress. Since Congress commenced tinkering up the mining laws the miners have let go and expend their energies in kicking. Some of the present laws show an utter ignorance of the subject and the conditions, and every effort made to amend them seems to make matters worse. For example, the Stewart bill, limiting to 40 acres applications for patent to placer claims. This is extremely unjust and inconsistent, and shows a want of knowledge on the subject, or an indifference towards this class of miners. There is no distinction made between the classes of mines where there is a very great difference in the mines and their requirement. Where a gravel deposit is exposed on the surface the pay ground is all in sight, and 40 acres is a good-sized hydraulic claim.

The principal drift mines, however, are to be found underlying a hard lava capping, several hundred feet in depth, in the main divides between the present rivers. The pay is found in narrow channels, generally running diagonally across the section lines; and as the law requires that the location of placer claims shall conform to the legal subdivisions of the Government surveys, it is doubtful, under these conditions, if a location of 160 acres would embrace more than 40 acres of pay ground on the channel. In this character of mines there is nothing in sight but the surface indications to guide the prospector. The position of the pay ground can only be determined by actual work in running long tunnels that cost many thousands of dollars. The inconsistency of this bill is manifest in the 40-acre clause, which would require four separate applications to obtain patent to one claim of 160 acres, located and held under the provisions of Sec. 2330 Revised Statutes, which the Stewart bill does not affect. Mr. Stewart can make a good speech and may be good at making laws for quartz miners, but for placer miners he is an outrageous failure.

Things are growing from bad to worse and more of it. The law in regard to placer claims should enlarge the miners' rights and privileges instead of restricting them. There is a wide departure in the present and proposed law and policy from that of the old miners. The old miners recognized the necessity of making a marked distinction between ravine, canyon, river and hill claims. The district laws in regard to each class were suitable, just and liberal. To encourage prospecting, the discoverer of new diggings was entitled to an extra claim (something the Government could well afford to imitate). The policy was to enlarge the miners' rights and the size of claims as the diggings become more difficult and expensive to develop and work. This proposed amendment in the Stewart bill reverses the whole policy, and if carried out will virtually put a stop to prospecting for and discovery of productive drift mines. The individual prospector's occupation is gone, since it requires a large capital to develop the drift mines. Without the restrictions of this bill on this class of mines, it is almost impossible to induce capital to assist the prospector in the discovery of new mines of this character.

The Law Department rulings and the whole policy of the Government tends to drive the energetic prospector and capitalist out of the country. They will go to British Columbia, South America and Mexico, where a more liberal and just policy prevails. It is only by a thorough organization of the miners that the present straggling elements can be systematized and the mining industry put on a solid and permanent basis, and the evils complained of remedied by and through a Government Department of Mines. To sum up: Establish a Department of Mines, with a head chief, who shall have exclusive control and management in detail of the mining industry and mineral lands. The President of the United States to appoint competent engineers from the U. S. Army to make examinations of all of the conditions in relation to the hydraulic mines, adopt plans, make estimates of cost, advise and assist the Secretary of Mines in devising some practical method by which the hydraulic problem can be solved.

There is another problem of more vital importance to the future of the mining interest than the hydraulic mines, which, if generally permitted to resume working, we think we can see the end. This other problem is in relation to the definite settlement of what is mineral land (on which subject I will give my opinion later on). There have been many long articles written and fine maps made of mining sections that have been worked for the past 40 years, describing and showing what the miners have done, none of which give a particle of definite and reliable information in regard to well-defined unexplored mineral lands. It is left to the pioneer—the old prospector—under all of the present adverse conditions, to strike out into the mountain gorges and over the barren lava ridges to discover a paying mine to determine the mineral character of the land. A Department of Mines established, the secretary should have all of the mineral lands laid off into suitable districts and appoint a competent mineral surveyor for each district, who should not be interested in any mines or mining operations. Under instructions from the secretary, the mineral surveyor should prepare a map showing all of the legally-located claims and the vacant lands. Let

all lands in the designated mineral districts be considered mineral until its real agricultural value can be established upon a hearing had before the joint mineral and agricultural departments.

The placer-mining laws could be greatly improved in some respects, in my opinion, by adopting a modified form of the old pre-emption law. The mineral surveyors should survey the township lines where they have not already been run.

The application to locate a mining claim should be made to the Department, which should order the surveyor to survey and prepare a map, showing the boundaries, marked by permanent monuments, of the claim sought to be located. No "annual assessment work" should be required. The claimant should be required to commence development work within three months after the survey is completed and continue the same with reasonable diligence. Failure to commence work for the period of six months after survey is made, or a cessation of work for a period of one year, should cancel the claim and subject it to relocation. The claimants should be allowed, in unmining for drift mines, three years in which to complete the development work, which time might be extended upon a showing, in good faith, before the Department. All claims now located, for which a patent has not been issued, should be required to be surveyed and come under the same regulations and requirements as new locations.

The mineral surveyor should be supplied with an official seal, and when he has completed the survey and prepared a map of the claim, he should deliver a copy to the claimants with his signature and seal attached. Where there is a contest between claimants, the surveyor should refuse to make any survey of a claim until the matter is definitely settled. If some such law as is here outlined were enacted, mining locations hereafter made, and many now made, would be in the interest of developing mines instead of, as at present under the "annual expenditure" clause, locations are made for speculative purposes, and are held on to, waiting for the other fellow to make a strike.

There are hundreds of claims throughout the mining sections of the State, that are held under the present law, that have not had \$100 expended on them in the past ten years that contributed one iota toward any practical development. Instead of having to pay for the measuring off of 40 yards of high-priced red tape, and filling half a dozen pigeon-holes full of affidavits, to obtain a patent, require a royalty of a small per cent to be paid the Government, on the gross product of a mine when developed. There should be a distinction made between the different classes of claims. The law in regard to quartz lodes or rock in place might be amended by extending the width of claims on the surface, and giving no rights to anything outside of vertical lines drawn perpendicularly from the surface boundaries in any direction downward.

For placer mines of the hydraulic class, the present law is good enough; that is, 20 acres to a claimant, limited to 160 acres for a company of not less than eight. The ravine—canyon—and shallow surface diggings, requiring no capital to develop and work, could be governed by local district laws not in conflict with the laws of Congress. The most difficult class to determine the proper extent and limits of a claim to is the drift mines of the channel system. It is supposed that an individual claimant will not locate a claim of this class, on account of the large expense incurred in running long tunnels. I think a reasonable extent for a claim of this class would be, for a company of not less than ten, permit to locate one mile in length on the course of a channel, without reference to the number of acres embraced. As to limitation, no two or more companies, by uniting or consolidating, should be permitted to hold more than two miles in length on a channel. As the Government recognizes but two classes of lands—the mineral and agricultural—it seems to me that there is as much of a necessity for a mineral as an agricultural department. Then all of the Government lands would be under the control and management of the two departments. Joint offices could be established, with an officer appointed from each department, who could make a specialty of the class of lands embraced in their respective departments. All of the duties of the Interior Department might be performed by the Mineral and Agricultural Departments jointly, and the Interior Department abolished. This would make a radical change in affairs, but a great change is needful. We want something more definite and systematic in regard to the mines and mineral lands; something in keeping with the progress of the times.

With a Department of Mines established and in systematic working order, and a thorough organization of the miners, the gold and silver mines of 1893 will make a good start for getting back into the old lines of prosperity, and mining again be considered an honorable and respectable vocation.

J. F. TALBOTT.

AMERICAN MINERS IN BRITISH COLUMBIA.—During the promiscuous selling of mineral claims and tractions of mineral claims that has been going on on the other side of the line, many interests have been sold to men who have no miner's license, says the Nelson (B. C.) *Miner*. This is absolutely fatal to their title; no court of law can protect them; they cannot sue to eject the jumper, and in defending a case in a suit of ejectment they would be non-suited at once. Ambiguous on many points, the law is perfectly clear on this. In order to acquire the legal status necessary to hold mining claims in British Columbia, a man must invest \$5 in a license. If he neglects to do this he may be throwing away thousands. Nor is there any injustice here. A mineral claim is not a piece of real property, but simply a claim on the Government for a grant of a certain piece of land after certain conditions have been complied with, and this tax of \$5 is one of these conditions. In the States a man cannot locate a claim unless he has taken out naturalization papers. Here he pays \$5 like the citizens of the country, and can go to work on the same terms.

GOING TO SOUTH AMERICA.—E. R. Ray, who had charge of the Providence mine previous to last September, has

been appointed superintendent of the Playa De Oro Mining Company's hydraulic mine, near Esmeralda, Ecuador, South America. A full outfit for the mine has been shipped from San Francisco. Mr. Ray has engaged the following men to go to the mine to work: Archie Patterson, V. V. Blodgett, Ed Ryan of North Bloomfield, John George of Grass Valley, and others. Mr. Ray leaves here Tuesday. The men will go later.—Nevada Co. Transcript.

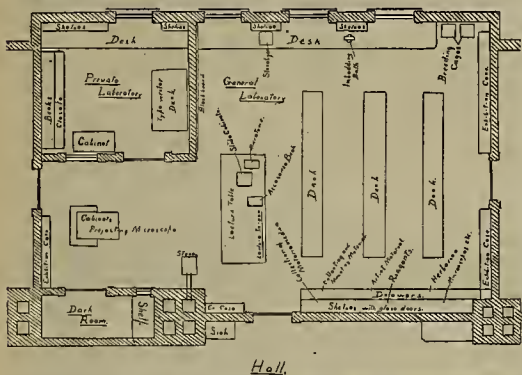

The University Laboratory of Entomology and Plant Diseases.

The growing demand for instruction in economic entomology and plant diseases has led to the equipment of a special laboratory for this class of studies in the Agricultural Experiment Station at the State University. Prof. C. W. Woodworth, who has charge of these subjects, recently prepared for *Science* a description and sketches of this arrangement and equipment, which we believe many readers of the *RURAL PRESS* will examine with interest. We reproduce from *Science* the full showing, as it embodies an arrangement for insect cases and a style of student's desk which may be suggestive to others who are working in this line on this coast.

There has recently been equipped at the University of California a laboratory for the study of the subject of plant diseases in its broadest sense; and, as there are but few if any others where the whole subject is taught as a unit, it may be well to give an outline of the equipment for this class of work.

We will not consider that part of the equipment for this work afforded by the grounds, orchard, nursery, gardens and greenhouses of the agricultural department, but confine ourselves to the laboratory proper. The subject of plant diseases is now, and will continue to be, associated with that of entomology, so that the same equipment, to a considerable extent, serves for the two subjects.

The laboratory-room is something over 20 x 30 feet, and is situated on the north side of the Experiment Station building. It is lighted by four windows, having an entirely unobstructed view, and so giving ample light for microscope work. A corner of the room is partitioned off for a private laboratory, and a closet is fitted with a ruby window, affording an opportunity for photo and blue-print work. The figure below will give a good idea of the arrangement of the room.

The windows are all fitted with heavy shades working in grooves, enabling one to darken the room very easily and quickly when the lantern is to be used for illustration. The views are projected on a screen of tracing-cloth, which is mounted on an ordinary spring-roller and is ordinarily rolled up out of the way.

Besides the benches near the windows, which are used by advanced students, there are also three long desks, 1½ feet wide by 12 in length, that have proven themselves so convenient that a sketch of one is presented. As can be seen on the plan, these are so constructed that at the side of each student, boxes, the size of those of the collection, may be used as drawers, or boards may be inserted, forming shelves.

The boxes used for the collection are made as shown in the accompanying figure, and are, from their peculiar construction, not liable to warp or crack, and so remain perfectly insect-proof. The cloth bearing for the glass is treated with corrosive sublimate, and the paste and glue used are arseniated. These boxes are kept in cabinets, the glass doors of which are fitted with a rabbited groove on all four sides, thus making them also dust and insect-proof.

The collections kept in these cabinets are arranged in three series. Series one is the systematic collection, where the organisms producing injuries to plants are grouped in the ordinary order, beginning with mammals and ending with the higher plants. The second series is the "host"

collection, where the various plants are taken up in an agricultural order, as, for instance, seed crops, fruit crops, etc., and the injuries to each particular crop illustrated. In the third series, the symptomatic collection, all diseases having a common symptom are brought together, thus all galls and distortions from whatever cause, or on whatever plant, are assembled and classified.

Besides these there are the beginnings of a cryptogamic herbarium in drawers and a collection representing the *materia medica* of plant diseases.

There are in the laboratory a sterilizer and all the other necessary apparatus for this class of bacteriological work. For microscopical and histological work there is also a good equipment, including paraffin bath, microtome suitable for the highest grade of work, compound microscopes and accessories, and a very good outfit of reagents.

All reagents, as far as possible, are kept in standard strengths, and the bottles marked to serve as graduates for dilution. Thus the chromic acid is made up in a large bottle into a 5 per cent solution. The 1 per cent solution is made by filling the bottle to contain it to a mark and adding water. Most of the chromic mixtures are made from the 1 per cent. The chromic-acetic killing mixture, for instance, is made, as is indicated on the label, from ½ per cent chromic acid to the first mark, 95 per cent alcohol to the second, and 10 per cent acetic acid to the neck. Mixtures liable to deteriorate are kept in small bottles, and such as the acid-alcohols, for decolorizing, are not kept mixed at all, but large homo vials are properly labeled and the mixtures made up as used.

This sketch gives merely the present condition of the laboratory; it is expected that apparatus will be added from time to time, as opportunity offers, and as it is needed for the work in hand. Indeed, there is considerable new apparatus at the present time being constructed for the laboratory.

Bezoar Stones.

Eliza Brightwen, of Great Stanmore, England, contributes the following article to *Science*:

The almost fabulous value set upon bezoars in olden days, and the medical virtues often attributed to them, invest these concretions, which are found in the alimentary canal of animals, both wild and domestic, with a certain amount of interest; and, although belief in their curative power has long since passed away, it may be deemed worth while to try and put together a few items about their history and uses.

The name of bezoar appears to be derived from the Persian *bad* (expelling) and *zahr* (poison), in allusion to the supposed virtues of the stone as a remedy for snake-bites and other wounds. Others again derive it from the name of the goat in which one variety is found.

These stones were introduced as medicines in the East by the Arabian physicians in the tenth century; there seems to be mention of them in Greek or Latin authors, but from the East their use gradually spread into Europe. They are referred to by Frampton as far back as 1580, and as late as 1746 these stones were in use in England, being found in the London *Pharmacopoeia* of that date. A severe blow to their reputation was administered by Ambrose Pare, who gave a dose of bezoar to a criminal condemned to death and to whom arsenic had been given; death, however, was the result.

In the Royal College of Surgeons' Museum of London, cases may be seen filled with all the various kinds of concretions which have been found in the intestines of different animals, including some very fine bezoars.

They may be roughly divided into six classes:

1. Balls composed of animal hairs.
2. Those composed of vegetable hairs.
3. The Oriental bezoars, composed of ellagic acid.
4. The Occidental bezoars, formed of resin or bezoardic acid.
5. Concretions of phosphate of magnesia, ammonia and earthy calculi.
6. Ambergris, found in the intestines of the whale.

We will briefly notice facts relating to each of these classes.

I. Animals, especially horses and oxen, are much given to licking each other and themselves, and the loose hairs being swallowed become felted into spherical balls of various sizes, generally black in color, with a hard, shiny surface, which often consists of phosphate of magnesia.

In the College of Surgeons' Museum there is one such hair-ball, taken out of an ox at Buenos Ayres, which measures 40 inches in circumference, and one of oval shape, found in a peccary, measures six inches by four in diameter.

II. Vegetable hair concretions are usually formed round some nucleus, such as a horse-nail, plumstone, or a piece of flint.

The setæ of the oat seem to have a constant tendency to form into spherical balls, and when felted they sometimes alternate with layers of phosphates, so that when divided the transverse sections of these are found to be marked by concentric lines.

III. The true Oriental bezoar is found in the wild goat of Persia (*Capra agagrus*), and is brought to India from the Persian gulf. In appearance it is black and hard, oval in shape, with a smooth surface, which has a peculiar shiny luster.

This stone consists entirely of ellagic acid, which is an

insoluble organic acid derived from certain constituents of the diets of the Persian goat. This acid can also be extracted from an infusion of gall-nuts when exposed to the air.

Bezoars were frequently set in hoops of gold or silver, having a chain of some metal by which they were suspended in the liquid to which it was desired they should impart their curative virtues.

Koemfer says: "In Persia all people of consequence possess one or more of these stones preserved with great care as valued treasures." A proof of their value is found in the fact that amongst the treasures sent to the Emperor Napoleon the First, by the Shah of Persia, were three bezoars valued at nearly £200.

Five hundred crowns (£125) have been given for one such stone, and Tavernier mentions one, weighing four ounces, which was sold for £150.

The diseases supposed to be cured by bezoars were of varied character, such as epilepsy, palpitation, vertigo, contagious fevers, etc. It is said to have been a custom in Persia to take a dose of powdered bezoar at the beginning of the year to protect the body from poison for the succeeding year.

They may have been useful perhaps in some cases, owing to the amount of bile contained in them, and also because they were sometimes steeped in infusions of active medicinal plants.

IV. The Occidental bezoar.

This is found in the goat of Peru and India, and, as a rule, it is larger, lighter in color, and for the most part without the peculiar black metallic luster of the true Oriental stone, and is of much less value. The chamois yields what is known as German bezoar, and another similar stone is found in the llamas of Peru.

The high price of the Oriental bezoar led to numerous imitations, for the most part made of chalk and pipe clay, frequently gilded to give the high polish of the Eastern stone.

By putting butter of antimony under the action of nitric acid, an artificial bezoar can be made, and other imitations were made of vegetable resin identical with the litho-fellic acid of M. Goebel, which he found in a calculus examined by him. These stones are sometimes called resino-bezoardic concretions.

The snake stones of the Portuguese were probably made by the Brahmins, who pretended that they were taken from behind the head of the Cobra da Capello. They were called Pedra di Cobra, and were made of calcined bone-earth finely powdered and mixed with musk and aromatic gums. They were probably of use when applied to wounds, although not quite in the way imagined, for, being highly porous and absorbent, when applied in quick succession to a recent snake bite, these stones would naturally draw out the poison by capillary action. When one stone fell off, another would be supplied until the wound was sucked dry. Koemfer says 28 tones were needed to be applied to effect a cure.

Fossil bezoars are found in Sicily in sand and clay-pits. They are concretions of a purple color, around some usually organic body, and are of the size of a walnut.

V. Concretions of phosphates of magnesia and ammonia. The consideration of these calculi would hardly come within the limits of this paper.

VI. Ambergris.

Concretions found in the Spermacetti whale. This substance is found also floating on the sea upon the coasts of Japan, Coromandel and Madagascar. It is of very light specific gravity, ash-colored, with black veins and spots. It is supposed to be a product of disease, as it is only found in dead or sickly whales.

One more so-called bezoar may be mentioned, and then, as far as is known, all the various kinds will have been touched upon.

In the Malay Peninsula there is sometimes found in the cocoon a stony concretion, properly called *Callappitte*, which is worn by the Malays as an amulet of great value. This is so like bezoar that it is sometimes mistaken for it, although a purely vegetable product.

MINT DIRECTOR'S REPORT.—The annual report of the Director of the Mint for 1892 shows the value of the gold product of the United States to be \$33,000,000, about the corresponding average of recent years. The product of silver was 58,000 ounces, of the commercial value of \$50,750,000, a falling off of 330,000 ounces from the preceding year. The amount of silver purchased by the Government during the year was 35,129,327 fine ounces, costing \$47,394,291, an average of 37½ cents per fine ounce. From it 6,323,345 silver dollars were coined during the year. The imports of gold aggregated \$13,165,056, and the exports \$76,735,592, a net loss of \$58,570,536. The silver imports amounted to \$31,450,968 and the exports \$37,541,301. The amount of money in circulation, exclusive of the amount in the Treasury, was \$1,611,321,753 on January 1st, an increase of \$18,923,124 during the year. There was an increase of over \$12,000,000 in the gold product of the world during the last calendar year. Of this \$2,500,000 was from Australia and over \$9,000,000 from South Africa. The total silver product of the world was increased about 7,650,000 ounces, occasioned chiefly by an increase of 4,600,000 ounces in the product of Mexican mines and 2,400,000 of Australian mines.

GEORGE W. LICHTENTHALER, aged 60 years, of Bloomington, Ill., died at the Russ House, Feb. 20th, of heart disease. About a month ago he began ailing, and for two weeks had been confined to his room. He was one of the most noted conchologists and marine botanists in the United States, and had spent the past 20 years in studying and collecting the shells and fauna of the Pacific coast from Alaska to Mexico. He had been connected with the Smithsonian Institution for many years. Most of his specimens were gathered by himself, and his collection of shells and marine plants is the finest private collection in the country, and is very valuable, as it is completely catalogued.

ROSE'S Modern Steam Engines UP TO DATE. A NEW, REVISED and ENLARGED JUST READY. EDITION

Modern Steam Engines. An Elementary treatise upon the Steam Engine, written in plain language for use in the workshop as well as in the drawing office; giving full explanations of the construction of Modern Steam Engines, including diagrams showing their actual operation; together with complete but simple explanations of the operation of various kinds of valves, valve motions, link motions, etc., thereby enabling the ordinary engineer to clearly understand the principles involved in their construction and use, and to plot out their movements upon the drawing board. By Joshua Rose, M. E. Illustrated by 453 engravings. A New, Revised, and Enlarged Edition. 357 pages, 4to. Price, \$6.00.

By mail free of postage, at the publication price, to any address in the world.

BY THE SAME AUTHOR

Mechanical Drawing Self-Taught. Comprising Instructions in the Selection and Preparation of Drawing Instruments, Elementary Instruction in Practical Mechanical Drawing; together with examples in simple Geometry and Elementary Mechanism, including Screw Threads, Gear Wheels, Mechanical Motions, Engines, and Boilers. By Joshua Rose, M. E. Illustrated by 330 engravings. Fourth edition, thoroughly revised and corrected. 8vo. 333 pages. Price.....\$4.00.

The Complete Practical Machinist. Embracing Lathe Work, Mill Work, Drills and Drilling, Taps and Dies, Hardening and Tempering, the Making and Use of Tools, Tool Grinding, Marking out Work, etc. By Joshua Rose, M. E. Illustrated by 354 engravings. Fifteenth edition thoroughly revised and in great part rewritten. 12mo. 439 pages. Price.....\$2.50.

The Slide Valve Practically Explained. Embracing Simple and Complete Practical Demonstrations of the Operation of each element in a Slide Valve Movement. By Joshua Rose, M. E. Illustrated by 35 engravings. 12mo. Price.....\$1.00.

Steam Boilers. A Practical Treatise on Boiler Construction and Examination. For the use of Practical Boiler Makers, Boiler Users and Inspectors; and embracing in plain figures all the calculations necessary in Designing and Classifying Steam Boilers. By Joshua Rose, M. E. Illustrated by 73 engravings. 8vo. 250 pages. Price.....\$2.50.

Illustrated Circulars, giving the full tables of contents of all the above works, sent free to any one who will apply.

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Our new revised Descriptive Catalogue of Practical and Scientific Books, 88 pages, 8vo, and our Catalogue of Books on Steam and the Steam Engine, Mechanics, Machinery, and Dynamical Engineering, and other Machinery, the whole covering every branch of Science applied to the Arts, sent free, and free of postage to any one in any part of the world who will furnish his address.

EDWARDS' WORKS ON THE STEAM ENGINE.

The American Marine Engineer. Theoretical and Practical. With Examples of the Latest and Most Approved Marine Practice. For the Use of Marine Engineers and Students. By Emory Edwards. Marine Engineers. Illustrated by 85 engravings. 12mo. 435 pages.....\$2.50.

Edwards' 600 Examination Questions and Answers. For Engineers and Firemen (Stationary and Marine) who desire to obtain a U. S. Government or State License. By Emory Edwards. Full bound in pocket book form, leather. 130 pages.....\$1.50.

The American Steam Engineer. Theoretical and Practical; with Examples of the Latest and Most Approved American Practice in the Design and Construction of Steam Engines and Boilers of Every Description. For the use of Engineers, Machinists, Boiler Makers, and Students. By Emory Edwards, M. E. Illustrated by 77 engravings. 12mo, 419 pages.....\$2.50.

Modern American Marine Engines, Boilers, and Screw Propellers. Their Design and Construction. Showing the Present Practice of the most Eminent Marine and Marine Engine Builders in the United States. By Emory Edwards. Illustrated by 30 large and elaborate plates. 4to.....\$5.00.

The Practical Steam Engineers' Guide in the Design, Construction and Management of American Stationary, Portable, and Steam Fire Engines, Steam Turbines, Boilers, Injectors, Governors, Indicators, Pistons and Rings, Safety Valves and Steam Gages. For the use of Engineers, Firemen and Steam Users. Illustrated by 119 engravings. 420 pages, 12mo.....\$2.50.

A Catechism of the Marine Steam Engine. For the use of Engineers, Firemen, and Mechanics. A Practical Work for Practical Men. Illustrated by 63 engravings. 12mo, 383 pages.....\$2.50.

Modern American Locomotive Engines. Their Design, Construction and Management. Illustrated by 78 engravings. 12mo, 383 pages.....\$2.50.

The above or any of our books sent by mail, free of postage, at the publication price, to any address in the world.

Illustrated circulars, showing full Tables of Contents of all of the above valuable books, will be sent free to any one in any part of the world who will send his address.

Our New and Revised Catalogue of Practical and Scientific Books, 88 pages, 8vo, as well as our other catalogues and circulars, the whole covering every branch of Science applied to the Arts, sent free, and free of postage, to any one in any part of the world who will furnish his address.

BUILDERS OF

"Sensible" Horse-Power Hoisting Whims.

(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, in hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake wheels at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and chocks, 1400 lbs.

Circulars giving Capacities and Prices furnished on application.

RAND DRILL COMPANY,

ROCK DRILLING, AIR COMPRESSING,

Mechanical Progress.

Gas-Saving Appliances.

The introduction of natural gas, its lavish use and the subsequent lessening supply, says the *American Manufacturer*, have done much to hasten the development of appliances by which a given quantity of gas may be made more effective. The efforts in this line seem to have been exerted in perfecting appliances adapted to the use of fuel gas for domestic purposes, for since the natural fuel was first put in mills and manufacturing establishments, very few improvements have been made in the manner of its use. The great waste naturally resulting from the belief that the supply was unlimited, compelled gas companies to take means of regulating the gas, and the adoption of meters followed. This, of course, did a great deal toward stopping the waste, but it seems that practically nothing has been done to increase the effectiveness of the supply. No material change was made in furnace construction, and although a number of burners for the saving of gas in mills have been patented, their adoption was very limited. The desire early shown by the gas companies to ultimately restrict the use of gas to domestic purposes entirely is perhaps the chief reason why there has been so little improvement made in the method of using it in iron and steel manufacturing lines.

The same cannot be said of the methods of using fuel gas in the household. With the advent of natural gas in houses, it was natural that immediate efforts toward ornamentation in the appliances should be made. When it became evident that the supply was growing smaller, appliances for the purpose of decreasing consumption soon appeared on the market. When natural gas was first put into houses, the former stoves and grates were used, the only change being perhaps the addition of a few bricks or lumps of fire-clay. The gas was used in the most indirect manner, and the largest amount possible was taken to do comparatively little work. But the decreasing fuel supply hastened improvements, so that during the past few years greatly-improved methods of using fuel gas have been brought out. While improvements have been made in using gas for heating alone, greater advancement has been made in the appliances by which it is used for culinary purposes. New stoves, ranges, etc., are being put upon the market. For some of these great claims are made, but, aside from this, it is evident that the time is fast approaching when coal will be no longer used in the kitchen. There are ranges on the market to-day on which the cooking for families of fully average size has been done in Pittsburgh, at an expense of 60 cents per month. This, of course, was with natural gas, but it has been shown that the ordinary city illuminating gas, at \$1 per 1000 feet, is cheaper for this purpose than coal at present prices. Even greater claims are made for one pattern of a gas stove now being sold. It is claimed that this will do the work referred to at a cost of not more than 40 cents per month, and an ordinary family baking can be done at a cost of one cent for fuel. This stove shows one peculiarity which marks the development of fuel gas. In it the heat is applied directly, and it has no flue connection. This plan is open to the objection that it vitiates the atmosphere of a room with the products of combustion.

In spite of this objection, the latest heating device brought to our notice is on the same principle. In this heater steam is also produced, and in answer to the objection stated, it is held that the amount of carbonic acid gas generated is insignificant. However this may be, it is certain that in the past few months a large number of heaters, constructed without regard to outlet, have been put in use. The fact that the use of fuel gas for domestic purposes is rapidly increasing is shown in the growing business in that line of manufacturing. One manufacturing firm recently received an order for 700 gas stoves from Salem, Mass. In the smaller cities throughout the country the use of fuel gas is growing greater each month, and the trade in gas-saving appliances will make great strides in the near future.

Shop Suggestions.

A pair of calipers has been devised with a star wheel in one of the legs, near the toe, so that five different settings can be obtained with a single pair. Instead of having so many lying around on the lathe board. The star wheel is made to turn turret fashion, and can have each of the five points ground to any fraction of an inch, or arranged to suit tapers and allowances for shrinkages. If a star

wheel can be made to work so handily, and give such fine results, there is room for another on the other foot, which could be made to combine in a large number of sizes on the differential principle.

How many there are who have no idea how fine a course the pitch of the cross-feed of a lathe may be. Every feed-screw should be graduated into degrees and made use of whenever the calipers are to be depended upon, for a lathe tool can be brought to the same setting so nearly twice alike by this means that the difference, if any, can always be brought on the safe side, and while a cut is being taken just to see how much is to be removed by the next chip, by testing with a scale, and set the tool so near the desired size the first time, with the cross-feed, that the second set will strike it sure, instead of approaching it gradually by a series of approximations that are simply tiresome.

Who is able to fix up a temporary tool that will work only in the lowest place when turning up a casting on the face plate? It takes but the combination of two or more simple levers, one of which is to trail about on the surface of the work.

Another problem in the same line lies in an arrangement of levers that will regulate an end mill in such a way that a cavity can be routed out to just contain a given form for die-sinking. It took a smart mechanic over ten years to hit on the right way, while another had no trouble to see through it in about ten minutes. It all depends on getting a comprehensive view of the problem to commence with, whether there are to be years of time wasted in groping around in the dark.—*Boston Journal of Commerce*.

A COTTON BELT.—At one of the great elevators in the West, says the *Manufacturers' Gazette*, a belt is in use which has a surface speed of nearly 2800 feet per minute, the driving pulley being of 16 feet diameter. The duck, which is the sole strength of the belt, is made from the heaviest and strongest staple cotton, weighing 32 ounces to the square yard. The friction cements the plies so tenaciously together as to render it well-nigh impossible to separate them. The cover will not crack, peel nor readily chafe, and excludes all moisture or dampness from penetrating and destroying the strength of the duck, while an even, smooth, metallic surface brings it in more perfect contact with the pulley, and enables it to transmit more horse-power than a belt having a rougher surface. It is deprived of stretch to an extent that will prevent trouble from its becoming loose and flabby on the pulleys, but not altogether devoid of elasticity. By means of a powerful hydraulic stretching device it is subjected to a great strain. At the same time, the polished plates of a hydraulic belt press are brought to bear and exert on its surface a pressure of about 2000 pounds to the square inch, under which process it is brought to an even and uniform thickness throughout. After this has been accomplished, it is, by vulcanization, rendered proof against moisture, dry rot or decay.

MANNESMANN LOCOMOTIVE BOILER TUBES.—According to the *Eisenbahn Zeitung*, the Austro-German Mannesmann Tube Works have gone into the manufacture of locomotive boiler tubes by the Mannesmann process on a large scale, with satisfactory results. At the beginning of last year the Royal Railroad Commissioners at Berlin began a series of careful tests of the physical properties of tubes for locomotive work, and, on the strength of the results obtained, have not only concluded to henceforth fit up all their new locomotives with these tubes, but have also given heavy orders for Mannesmann tubes to be used for renewals. As a rather interesting and noteworthy novelty recently introduced in the manufacture of the tubes, the *Eisenbahn Zeitung* cites the fact that, while the tubes are of uniform outside diameter, they are made with the inside diameters varying from end to end, giving a tapering interior, and a consequently greater thickness of the tube walls at one end than at the other. Advantage is to be taken of this feature by placing the tube ends with the greater weight of metal toward the fire box end of the boiler, where there is apt to be most wear. At the smoke-box end, then, there would be less tube thickness, which, it is argued, would be conducive to a better utilization of the available heat of the cooler products of combustion.—*Railroad Gazette*.

FINE MECHANICAL WORK.—An instance of remarkably fine mechanical work is that described by Prof. Rowland, the distinguished microscopist, says an exchange, who has now succeeded in manufacturing a screw for his dividing engine which is said to be more nearly perfect than any other of the kind ever produced. It is made of the best steel, is $1\frac{1}{2}$ inches in diameter, 17 inches long, and with 20 threads per inch; was

first cut in a lathe in the ordinary manner, then ground by using a nut equal to it in length, which was placed on it with washed emery, and the screw revolved under a bath of water and oil maintained at a constant temperature. The grinding required about three weeks. It is to be used mainly in rolling gratings for spectroscopes, and it is thought will be capable of ruling a million of lines to an inch. In the head attached to the screw there are a thousand notches, so that the movement of a notch advances the thread 1-20,000 of an inch. It may be remarked that M. Behrens has lately stated to the Amsterdam Academy of Sciences that, under high powers of the microscope, the network in hardened steel may be made visible on polished slices without etching or annealing—the dark, sinuous lines answering to the bright ones shown by Sorby on etched slices, and it is proved that hardened steel contains hard granules bound up in a matrix of soft iron.

Scientific Progress.

Chemistry of Storage Batteries.

If a plate of lead, coated with peroxide of lead, be placed in sulphuric acid, it soon becomes covered with sulphate of lead as a result of local currents between the peroxide and the lead, or by simple chemical solution, so that in Plante and Faure's battery the peroxide is gradually destroyed independently of the main current. This action takes place slowly, as the sulphate of lead is deposited between the lead and the peroxide, and diminishes the local current. If no sulphate of lead were formed, the peroxide of lead would soon be consumed. The sulphate of lead is subsequently reduced by the hydrogen, forming spongy lead. By repeated charging, the quantity of finely divided substance increases.

If two electrodes that are covered with sulphate of lead be immersed in dilute sulphuric acid, and a current passed through them, one will become covered with spongy lead, the other with peroxide formed from the sulphate.

The peroxide formed upon the positive lead plate of the secondary battery becomes covered with an impenetrable layer which prevents the further production of peroxide; hence Plante leaves his battery at rest, which favors this formation of sulphate of lead.

In this way all the sulphuric acid can easily be taken out of the solution. A considerable quantity of oxygen will not be absorbed. According to Kabath, the interior plates of lead foil are rapidly crumbled, but the particles remain hanging between the other plates.

Dr. Gladstone ascertained that the local action which corrodes the lead plate supporting the peroxide of lead, thus impairing the value of the battery, took place during the formation of the battery, during the repose, and during the discharge, and it was an important question to determine what modification of the present arrangements would minimize or prevent local action. Dr. Gladstone presumed that the sulphate of lead formed in the secondary batteries could be oxidized as well as reduced, to yield peroxide of lead in the former, and spongy lead in the latter case, and thus to re-establish the initial state of the battery. The oxidation of the sulphate of lead was not doubted, but Sir W. Thomson said he had only been able to obtain a very spurious reduction, while Prof. Lodge failed in realizing any reduction of the lead sulphate. As this reduction was one point of Dr. G.'s explanation, both he and Mr. Tribe, who has always shared Dr. G.'s researches in this field, and Prof. Lodge, repeated their experiments, and *Nature* had communications from these two gentlemen, which both adhered to their former opinions. The question also occupied Sir William Thomson, who, experimenting with two platinum plates coated with sulphate of lead, making one the positive, the other the negative electrode, observed the oxidation of the sulphate on the former, but found a doubtful indication of a reduction on the latter electrode, though the action had been continued for six weeks. Dr. G. attached 20 grammes of the white sulphate of lead to the negative plate by binding it with parchment paper, and passed a continuous current of one ampere through the dilute acid in which were both plates. The greater part of the hydrogen generated at the negative plate escaped, but after 24 hours the gray metallic lead became visible through the wet parchment, and at end of ten days the whole of the sulphate was reduced to a gray spongy metal. Dr. G. convinced himself by analysis that the spongy mass was really nothing but lead. Dr. Gladstone thinks that the reduction of the sulphate of lead is an absolute fact, although it does not take place so easily as

the oxidation. Prof. Lodge recommenced his experiments with a view to ascertain, not whether the sulphate of lead was reduced in bulk by the nascent hydrogen, but whether any traces of metallic lead could be obtained on the negative plate.

Prof. Lodge immersed platinum electrodes in a paste of sulphate of lead, the two electrodes being about two inches apart. The paste was obtained by precipitating with sulphuric acid dissolved carbonate of lead, to secure a fine state of subdivision. When three Leclanche cells were used, the evolution of gas from both plates was powerful enough to form a halo round each, filled with only turbid liquid; but both plates showed a distinct but extremely thin coating of peroxide and metallic lead respectively. To avoid the strong evolution of gas, two cells only were used; the growth of peroxide was abundant, but the formation of metallic lead on the negative plate was even less perceptible than before, and the metallic lead was better deposited from the liquid above the paste than from the paste itself. Still, when electrolyzing a clear solution of sulphate of lead in dilute sulphuric acid, the solution being concentrated as much as possible with so insoluble a body as sulphate of lead, no effect was noticed. The experiment was modified by dipping the platinum plates into the clear liquid above the paste, barely letting them touch the mass; then the negative plate appeared blackened, while the positive one hardly received any deposit of peroxide except along its bottom edge. The possibility of a reduction is evident, but of no practical value if the deposit of one week could be dissolved in one drop of nitric acid, and if this solution gave no more than a faint precipitate with sulphuric acid. One might get over the contradiction in these two statements by supposing that Dr. G. was more successful as he secured a close contact between the electrode and the sulphate coating, while, in Prof. L.'s arrangement, the gas bubbles kept the sulphate particles away from the platinum plate. But some of Prof. L.'s observations do not admit of this interpretation, and we can hardly assume such conditions to correspond to those in a storage battery in which the supposition of a reduction seems almost unavoidable.—*Recent Advances in Electricity*.

The Wetting of Coal.

The scientist asserts that there is no economy to be gained by wetting coal, because, if the water is decomposed, it will require as much heat to effect the decomposition as is yielded by the reunion or combustion of the gases. There would rather, he says, be a loss, from the fact that the steam or vapor into which the water would be converted, whether dissociation took place or not, would convey heat away on its passage to the stack. On the other hand, the man who is constantly handling soft coal will tell you that it burns better and goes further if judiciously moistened, and he knows it.

An explanation has been suggested in the fact that wetting retards the immediate and violent distillation which follows the introduction of new fuel, and that under these circumstances decomposition takes place in the furnace, where the sheets get heat enough anyway, and the reunion or combustion of the dissociated gases takes place further along in their passage to the stack, where the heat can be better applied. In other words, the water, by its decomposition, takes heat from the furnace, and by its subsequent combustion distributes it over the heating surface of the boiler to better advantage than if it were concentrated under the first fire sheet.

Recent experiments, too, have shown that a considerable quantity of aqueous vapor is necessary to facilitate the union of furnace gases with the oxygen of the air. It may be to this fact, rather than to the extra flow of air induced, that the steam jet owes its efficiency as a smoke preventer.—*Power*.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower Engine and 45-horsepower Boiler with Over-cruiser and other machinery. Mill Scales, Asaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

C. W. MOULTROP,
225 Mission St., San Francisco,
Model Maker, Draughtsman Blue Prints,
Models of Machines, Etc.
MODELS OF MINING PROPERTY.

Professional.

Steam Engines, Saw Mills, Mining Machinery, Dredging Machines, Rock Crushers, Cable Railway Machinery, Elliptical Air Brake Co's Patent Steam and Hydraulic Elevators, Air Cushions and Air Brakes. POSITIVE SAFETIES. Improved Ram Elevators, Sidewalk and Hand Hoists. B. E. Hendricks' Patent Automatic Safety Catches.
Machines of all kinds Made and Repaired.
Orders Solicited.

HOME STUDY OF MECHANICS.
To commence, students only need to know how to read and write.
Send for FREE circular to The Correspondence School of Mechanics, Scranton, Pa.

TUBBS CORDAGE CO.
(A Corporation.)
Constantly on hand a full assortment of Manila Ropes, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.
611 & 613 Front St., San Francisco, Cal.

Metallurgy and Ores.

SELBY SMELTING and LEAD CO.,
416 Montgomery St., San Francisco

GOLD AND SILVER REFINERY And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurates

— MANUFACTURERS OF —
BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, Etc., Etc.
ALSO MANUFACTURERS OF

Standard Shot-Gun Cartridges.
Under Chamberlin Patent.

JOHN TAYLOR & CO.,
IMPORTERS AND DEALERS IN
ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.
68 & 65 First St., cor. Mission, San Francisco
We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.
Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.
JOHN TAYLOR & CO.

NEW DISCOVERY.
Mines Revived and Miners Enriched
By the wonderful MacArthur-Forrest Process, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. Tabor, Pres.; LONARD GOW, V. Pres.; H. A. JONES, 24 V. Pres.; P. GOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Secy.; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
The Glasgow Works, Limited, Scotland, also in Australia, South Africa, New Zealand, Queensland, Etc.
DENVER WORKS: On the D. & R. G. R. R., near the Broadway Electric R. R. Depot.
IMCARTHUR-FOREST PROCESS

General Office of Company:
Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingston Gold Mining Co., Boulder Co., Colo.; The Fuzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercur Gold Mining Co., Fairfield, Utah; Champie's Mines, Humboldt District, Yavapai County, Ariz.; The Crowned King and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Co., Gold Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the Mac Arthur-Forrest process
We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patent covering this process.
If you desire an experimental test communicate with the secretary.

If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.
We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubs especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$3.00 per ton.
The most desirable class of ores for this process the so-called refractory gold ores, pyrites, hematites manganese and tellurium. We have also treated successfully dry silver ores.
We will be pleased to answer any inquiries and furnish any desired information. Address,
T. L. WISWALL,
P. O. Box 926. Gen. Mgr and Secretary.

WELLMACHY All kinds, Water, Gas, Oil, Mining, Ditching, Pumping Wind and Steam Heating Boilers, &c. Will analyze you to send 25c. for Encyclopedia, of 1500 Engravings. The American Well Works, Aurora, Ill., also, Chicago, Ill.; Dallas, Tex.; Sydney, N. S. W.

PUBLIC SALE

— OF A —

SILVER REDUCTION PLANT

THE TOMBSTONE MILL AND MINING COMPANY, having no further use for its mill and furnace at Charleston, will sell at public sale, on the property,

TUESDAY, MARCH 21, 1893, AT 3 P. M.,

To the highest bidder for cash: All of the property known as "The Charleston Mills," real, personal and mixed; consisting of one 20 and one 15-stamp silver mill; one 26-ton water-jacket lead smelter; dwelling house and other buildings; and including the land, flume, ditch and water right pertaining thereto; situated on the San Pedro river, nine miles from Tombstone, Cochise county, Arizona.
Terms of payment will be made known at the sale and ample time allowed to investigate the title to the property.
By order of the Board of Directors of the Tombstone Mill and Mining Company,
W. J. CHEYNEY, Secretary, Tombstone, Arizona.

WORLD'S FAIR REDUCTION.

San Francisco Pioneer Screen Works
JOHN W. QUICK, Proprietor.

GREAT REDUCTION IN MINING SCREENS UNTIL the opening of the World's Fair. Perforated Sheet Metals, Steel, Russia Iron, Zinc, Copper, Brass, Etc. Mining Screens a Specialty.
221 & 223 First St., San Francisco.

QUICKSILVER

— FOR SALE BY —

The Eureka Company of San Francisco,
Room 1,
429 CALIFORNIA ST., SAN FRANCISCO.

HOISTING ENGINES FOR MINES

1, 2, or 4 Drums, with Reversible Link Motion or Pat. Improved Friction.

MADE ONLY BY THE

— AND —
CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.
H. D. MORRIS, Agent, 220 Fremont St., San Francisco.
Special attention given to the purchase of Mine and Mill supplied.

Stamp Cam

Electricity.

Electricity and Disease.

The application of electricity in medicine and surgery has kept pace with its service in commerce and industry. It has had its quacks and frauds, and in many instances acted as a magician with public confidence, and as a confidence man with its dollars. With these exceptions and the usual squad of impostors and dupes, the service of electricity in the healing arts of the physician has been of considerable value. Its possibilities as a remedial agent are as yet not in sight or perspective limit. In apparatus, device, forms of current and new methods, every year sees an increase and improvement. By aid of its light the physician can explore all parts of the human economy, and by the use of the endoscope can scrutinize the internal walls of the stomach, and dart its search-light over the abdominal department, where disease in its embryonic conditions has hitherto enjoyed immunity from inspection. The electric needle is used to decompose tumors, coagulate aneurisms and remove vagrant hairs and freckles from territory in which they have no claims of citizenship. The electro-magnet extracts iron or steel from the eye, and the electric motor turns the drill of the dentist when excavating a troublesome molar. As a means of diagnosis it has proven of considerable service, and in the surgery of the brain and spinal cord, has a special value. The introduction of drugs into the human body *via* the skin is an added service in electric medication, and has done much, not only in the alleviation of pain, but in the prolonging of life. In some disorders of the nervous system its intrinsic value is a matter of dispute, and some claims made by practitioners on that score have to be accepted on faith. Enough of evidence is, however, on hand to illustrate the value of this potent and mysterious force that can find its way in the muscle, bone, nerve and viscera of the human economy, and search out the secrets of cells, tissue and all the functional organisms in the physiology of man. In this aspect, electricity is beneficent and also suggestive of the thought held as yet in suspensive conditions, that in what is known as "the secret of life" the subtle and mysterious force known as electricity may be an affiliation if not an exposition. Electricity may forever remain a comparative mystery, but to those who know most of the little already known of this potent energy, the lines of discovery are constantly vibrating with what, if a problem to-day, ceases to be so to-morrow. The Age of Steel.

Electricity on Canals.

The question of equipping canals with electricity is now being agitated in several States. Governor Flower, of New York, has recommended that Erie canal be so equipped. He thinks that \$1,000,000 will do it, \$700,000 for 14 power stations and \$300,000 for putting up the poles and wiring them. He believes that current can be furnished the boats for 60 cents per craft per day. This would greatly reduced the cost of operating canal boats and would be a boon to the owners of such craft. Repairing the roadway is now a great expense to the State. This, the Governor believes, can be saved, and with the earnings of the electrical system applied to it, made to liquidate the bonds.

The project is entirely feasible. In addition to the benefits derived from installing a motive power cheaper than mule flesh, the mechanical and electrical trades would receive an impetus that would be felt everywhere. The construction of the immense engines, boilers and dynamos for the power stations would help to fill the shops with work. Their maintenance would give constant employment to skilled men, and the muleteers who now work for about \$10 per month and board, would, if they continued on the canal, have to acquire some knowledge of electricity or mechanics. The building of the motors for the boats would furnish a very large amount of work, and open up new fields for invention and design.

Taking every side of the question into account, no more feasible enterprise for a State, canal traffic and for the promotion of mechanical and manufacturing business generally could be entered into.—Scientific Machinist.

HOW IT IS DONE.—An interesting example of bringing of energy of a water privilege to a locality more convenient for manufacturing purposes is that reported of the Nonotuck Silk Company, which is supplying its mills at Leeds and Haydenville with electric-power generated at a rocky gorge a

third of a mile from one mill and $1\frac{3}{4}$ miles from the other mill. In one mill the motors directly drive lines of shafting, while in the other mill they act as auxiliary to the water-wheels and regulate them, and also with the engine at times. The motor belts upon the main shaft, which is driven by two water-wheels, the latter being run at full gait without any regulator, but the motor serves as a regulator, running at uniform speed and furnishing the remainder of the power. On the water falling too low for the water-wheels and motor to run the mill, a steam engine is hauled to the main shaft, the motor and water-wheels furnishing their full capacity and the engine regulating the whole. An important precaution, however, in this arrangement is mentioned, namely, that of setting the governor on the engine for a speed slightly greater than its proportion to the motor and water-wheels, so that it will lead, and also to prevent the motor tending to do more than its capacity.

The Conductivity of Insulating Bodies.

The effect of the physical condition of substances upon their dielectric properties is one that is deserving of more study than it seems to have received. In the *Philosophical Magazine*, M. Edward Branley, M. D., calls attention to the fact that very thin films of insulating bodies seem to become conducting, and that good conducting material opposes great resistance to the passage of a current when inserted in its path in a pulverulent condition. Thus far there is nothing in his statements that might not have been arrived at by *a priori* reasoning; but that the conductivity of the pulverulent mass may be measurably restored by the discharge of a Leyden jar in the vicinity and destroyed again by a slight mechanical shock, while not new, could scarcely have been anticipated by theory. The phenomena having been demonstrated, however, one or two theories at once suggest themselves as plausible explanations of their cause. There are one or two other phenomena of thin films or pulverulent dielectrics, however, whose explanation is not so obvious. For instance, if the two ends of a circuit be varnished with shellac, and after the latter is thoroughly dry be brought into intimate contact, the insulation against low potentials is practically perfect. But place this junction in an atmosphere of pure hydrogen gas, the resistance is gradually lowered until comparatively good conductivity is established, only to be destroyed again equally gradually when the hydrogen is removed.

Neither mechanical shocks nor moderate increase of temperature seem to have any perceptible effect upon the rise or subsidence of conductivity. But if the treatment with hydrogen be repeated after complete resumption of the insulating state in air, the junction cannot be restored to the same degree of conductivity it was made to assume in the first instance, and the effect of the hydrogen gradually decreases with each subsequent application, until it seems to disappear entirely. Carbonic oxide and artificial marsh gas produce the same effect, though to less degree, while natural marsh gas seems to be inert. The presence of carbonic acid, nitrogen, oxygen or other electro-negative gases, even in considerable proportion with the hydrogen, seem to have no effect upon the phenomena except what might be reasonably attributable to the dilution caused by their presence. On the other hand, if finely-pulverized, hard glass be imbedded in the two ends of the circuit, and they be brought together again as before, and hydrogen applied, a much higher conductivity will be attained than in the case where shellac was the dielectric; but it will not be assumed gradually as before, but in a series of impulses each succeeded by a non-conducting state, these electric impulses becoming more and more frequent until the current finally passes continuously with nearly the same freedom as it would were the conductor unbroken. On removing the hydrogen, the junction remains conducting much longer than where shellac is used, but loses its conductivity completely and instantaneously. Thus many substances have been tried with similar results, but differing in degree. But the manner of assuming conductivity and of losing it again seems to differ with each, and to be in a measure characteristic of the substance employed. A satisfactory explanation of these phenomena has not yet been suggested.

ONE of the new features of electric medication, says the *New York Sun*, is the introduction of drugs into the human body through the skin. This is done by placing solutions of any drug upon a sponge, which is made the positive pole and placed against the skin. When the current is turned on, the drug is actually driven through the skin into

the tissues. The application is not at all painful. Thus cocaine has been driven in over a painful nerve, and neuralgias have been relieved by it. Many other drugs have been used in this way. This property of electricity is known as cataphoresis.

Useful Information.

Yellow Pine and California Building Lumber.

In early times in California, when the saw-mill business was not reduced to such a science as it is now, many mill-owners placed their plants in the foot hills. They cut everything that came along, without regard to quality or usefulness. In these foot-hill districts the timber is of an inferior grade, spongy and liable to twist and split if exposed to the elements, and because of the many disadvantages of this lumber it has been given the name, bull-pine, a name which suggests the true nature of the wood.

All lumber from the foot-hills is of a similar character to bull-pine and is consequently condemned by our architects and builders. Of all pines, sugar pine is the most favored, and even that, when taken from the lower districts, is of an inferior grade.

During the past 15 or 20 years the mills have had to go back or higher into the mountains and the temperature, winds and snow exercise such an influence upon the timber that the mills of a higher altitude are able to produce a pine superior to any of the Eastern woods. Yellow pine, grown in the northern California mountains, is as firm and durable as any of the pines grown in the eastern part of the United States.

For standing finish, stepping, flooring, etc., and places where durability and strength are required, it has no superior among the soft woods. Another point in favor of it is its tendency to become light in color with age, while Oregon pine becomes darker under the same circumstances. The germs of disease cannot get such a hold on yellow pine as they can in redwood, white cedar, etc., and the delicate pitchy odor peculiar to yellow pine makes it its own disinfectant and especially adapts it to use in living rooms and hospitals.

I will venture to say from my own personal observations, during the past 25 years, that slash grain, No. 2, yellow pine flooring will outlast the vertical grain in Oregon pine or fir, for the reason that it wears smooth and does not splinter, while in vertical grain Oregon pine the soft fiber between the hard grain shrinks away and causes the piece to become rough and full of splinters. Scrubbing has no rotting effect but will make it whiter, while an Oregon pine floor will rot under an ordinary amount of scrubbing. While it is true that yellow pine costs a trifle more than Oregon pine, the benefits are increased four-fold.

If you will but notice the percentage of yellow sugar pine used in steamboat work, it will furnish convincing proof of the value of it for rough work and its ability to hold paint in spite of the many immersions in salt water.

A few words more in regard to our California woods. We have what is called Oregon pine or red fir and white fir or spruce. Our mountain red fir is better than Oregon or fir pine for railroad bridges and seems an excellent lumber for holding its shape, strength, etc. I mention these facts for the benefit of those who think we produce nothing but redwood and sugar pine.

Much more could be said in regard to our woods in general, but my humble pen is not equal to the task, of what is known by our California lumbermen in regard to a product that will some day form a great factor in our commerce and bring California among the first ranks of lumber-producing States.—Cor. California Architect and Building News.

Cost of Furs.

A skin of the sea-otter has been sold for as much as \$775. Sable skins, little bigger than a man's hand, have been sold for \$100 each, which is proportionately more expensive than the skin of the sea-otter. A mantle of this valuable sable fur was a gift to the present Empress of Russia on her coronation by the town of Vitouisk, in that country. It weighed 16 ounces and is valued at \$60,000.

The skin of an elephant, when tanned, is very expensive, the tanning taking about six months, says the *Boston Globe*. Articles made from elephant hides are costly luxuries.

The skin of a silver fox, otherwise called black fox, varies in price from \$50 to \$200. The whole number obtained annually amounts to only 2000, of which about 1600

are imported into England. La Hontan states that in his time the skin of the silver fox was worth its weight in gold, and an unusually fine skin has been sold in the London market for \$250.

Of the species of marten which is distinguished as the Russian sable, the darkest skins command \$150 each. Inferior skins of the same animal fetch as little as from \$1 to \$2.

A skin of the tiger of North China, which has hair from two to three inches long, and frequently measures from 10 to 14 feet in length, is valued at from \$50 to \$100.

Among expensive furs, Mrs. Mackay owns a set of black fox which cost \$14,000.—Chicago News-Record.

"Heart Failure" and Stomach Stuffing.

A physician writing to the *Medical Brief* says: I wish to say a few words about heart failure. We almost daily see reports of deaths attributed to heart failure. Now, what I wish to ask is, what is it the heart fails to do? I have always considered the heart the most perfect organ of the animal economy, and one that never shirks its duty. It commences its labors during the early stages of pregnancy, and goes on until the last moment of life, without one second's rest, night or day, often without the intermission of a single pulsation for 100 years or more. At every beat it propels two ounces of blood through its structure. At 75 pulsations per minute, nine pounds of blood is sucked in, and pumped out. Every hour, 540 pounds; every day, 12,960 pounds; every year, 4,730,400 pounds; every 100 years, 473,040,000 pounds. Verily a good organ and all performed without one moment's rest.

Now, the heart has the very meanest and most contemptible neighbor that ever an organ had, namely, the stomach; a drunkard, a glutton, a trespasser, and almost everything else as bad. Verily it ought to be walled in and compelled to keep on its own grounds.

The stomach lies directly under the heart, with only the diaphragm between, and when it fills with gas it is like a small balloon, and lifts up till it interferes directly with the heart's action. The stomach never generates gas but when filled with undigested food fermentation takes place and gas is formed, and the interference depends upon the amount of gas in the stomach. To overcome this obstruction, the heart has to exert itself in proportion to the interference, more blood is sent to the brain, and the following symptoms are the result: A dizzy head, a flushed face, a loss of sight, spots or blurs before the eyes, flashes of light, zigzag lines or chains, etc., often followed by the most severe headache. These symptoms are usually relieved when the gas is expelled from the stomach.

Now, when this upward pressure upon the heart becomes excessive, more dangerous symptoms supervene, a larger quantity of blood is sent to the brain, some vessel ruptures and a blood clot in the brain is the result, and the patient dies of apoplexy, or, if he lives, is a cripple for life.

When a sick person, or an old one, or one with feeble digestion sleeps, digestion is nearly or quite suspended, but fermentation goes on, and the gas is generated as before stated.

A man is found dead in bed, and the medical attendant pronounces it the result of heart failure, and such is the certificate of burial given. Now, the man was out, partook of a late supper, and ate roast beef, turkey, chicken, lobsters, oysters, mince pie, plum pudding, ice cream, cake, an orange, nuts and raisins, three or four cups of coffee, etc., went home at midnight, retired, and dies of heart failure before 9 o'clock the next morning. What did the heart fail to do?

Again, a man is sick with typhoid fever or pneumonia, or almost any other disease, and died, it is said, from heart failure; but what has his diet been during his sickness? At present it is very fashionable to commence at once with what might well be called the stuffing process—iced milk, which is so cool and grateful to the patient, from three pints to one gallon during the day and night. But if allowed to make a suggestion, I would say that in place of it, clam chowder, thickened with gravel, stones, eggs, beef tea, whisky, cream and all the other good things the poor patient can be induced to swallow.

Are You Going East?

Take the Santa Fe route. You will find it to your interest to call on or address the undersigned before purchasing tickets. No other line crossing the continent can offer you a trip combining equal comfort and pleasure. The only line running Pullman palace and tourist sleeping cars through to Chicago on the same train every day without change. Personally conducted excursion through to Boston leave every Tuesday. W. A. BISSELL, 650 Market street, Chronicle Building, San Francisco.

...SOLE MANUFACTURERS OF...

KENDALL'S PATENT
QUARTZ MILLS.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past 14 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the price we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that is claimed for it and give entire satisfaction.

Patent Agency

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

CONCENTRATORS

ARE OUR SPECIALTIES.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle leading toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE KEYSTONE.—Ledger, Feb. 25: The Keystone mine at Amador City is running its 40 stamps upon low-grade rock, taken from the old stopes. The company is not opening up any new ground at present, but expects to do so in the near future. Persons closely connected with the management do not know of any change in the ownership of the property, as recently reported, and assert that at the annual election, which took place in the latter part of January, the old officers were elected with the exception of the secretary, who resigned in December. It is probable that the report of the change of ownership is based on the sale of some of the stock.

THE BUNKER HILL.—Mr. Fisher, the receiver of the defunct Philadelphia Bank, who purchased the stock of the Bunker Hill at the receiver's sale, has arranged with some Eastern mining men and capitalists to lease the Bunker Hill property to them for a term of years. They were expected out here during this week to look over the property. If they find it satisfactory, the intention is to go to work immediately and carry the Mayflower shaft down and put the entire plant in operation just as soon as it is possible to get timbers and other necessary supplies.

MICELLANEOUS.—W. C. Minear investigated the condition of the water in the Volunteer shaft on Monday, and found that it was lowering rapidly. In about a week longer he expects to resume work. Mr. Minear is very anxious to get back to work, for when driven out by the water he had just struck a vein which appeared to be a portion of a valuable ledge of ore. The Gwinn mine, on the other side of the river, has been laying idle for a number of years, but at the present time a hoard on it is held by a gentleman who is in hopes of interesting Boston capitalists in opening it up once more. J. B. Francis is running a prospect tunnel into the hill on W. P. Peek's property. He is in hopes of finding a good ledge of quartz. The contractors will finish the third and 100 feet of tunnel at the Farrell mine some time next week if nothing unforeseen happens. The people at the Hardenburg are at work in the old shaft investigating its condition. The Kennedy people are still sinking in the north shaft through very hard rock.

HARDENBURG.—Amador Dispatch, Feb. 25: The proprietors of the Hardenburg mine have decided to open out the ore shaft again instead of sinking a new one, and the work of cleaning it out was commenced this morning.

Calaveras.

NORFOLK.—San Andreas Citizen, Feb. 25: F. B. Morse has just returned from the city, and it is stated, operations at the Norfolk mine will be resumed at once. The signs of the times are that this summer will be a lively period in the mining history of the camp, and in fact there never was a more general interest manifested in quartz than at present. Several minor transfers of property have taken place recently, while mine owners are promptly doing their assessment work, preparatory to the boom that is expected.

El Dorado.

MILL.—Georgetown Gazette, Feb. 25: Supt. J. W. Tryon is now making preparations to erect a ten stamp mill on the Alpha mine, located about one-half mile below the Taylor.

Nevada.

SOUTH IDAHO MINE.—Timings, Feb. 24: The South Idaho mine is the scene of active operations at the present time; several men are at work, some grading off the ground preparatory to erecting buildings, some framing immense timbers to be used in timbering the shaft, while others are cutting down the old shaft to larger dimensions and putting in timbers. The shaft is to be a three-compartment one, 5 feet by 12 feet in the clear; the timbers are spruce and 10 by 12. The company intends to timber the shaft down to the present depth and then continue to sink. The ledge in the shaft is a good-looking one, 3 feet in size, the walls being 5 feet apart. The character of the rock and the pitch of the ledge is very similar to that found in the famous Idaho. The mine is a large one, being the consolidation of two claims, each 1500 feet long, making the mine 3000 feet on the lode. In conversation with a number of experts and practical miners, we are led to believe that there is no better prospect in the State and we expect soon to hear from the South Idaho as a regular dividend payer.

FINE ROCK.—Thomas Schofield brought some very fine looking quartz to town to-day from the Reunion mine, which is situated about two miles southwest of the North Star. The claim is owned by Mr. Schofield and Mr. Wickes. A shaft has been sunk on the property and the rock shown was taken from a strigier of the main ledge. The rock was covered with free gold and the main ledge is of good size and quality.

CHAMPION DIVIDEND.—The Champion Mining Co., of Nevada City, has declared another dividend of ten cents per share. This mine is a regular dividend payer of late, and the plucky owners are getting returns from their investment after long and patient waiting.

THE GREEN MOUNTAIN.—Foothill Tidings, Feb. 24: Dan Coffin has bonded the Green Mountain mine on Osborn Hill for a company composed of Sacramento and San Francisco capitalists, who will begin operations as soon as the weather will permit. A new shaft will be sunk and the complete hoisting and pumping

outfit will be placed on the ground. The Green Mountain claim is consolidated with the Sanders' claim and the two claims have produced in all, as near as can be ascertained, \$166,664 20. The mine has never been worked systematically and the new company intends to open it up in the very best shape. It was shut down in 1864, again in 1871, in 1873, and again in 1886. Every time it has been worked it has paid well. The ledge is from six inches to three feet in thickness, and the rock has paid from \$25 to nearly \$400 per ton; all the rock that was taken out averaged \$95 per ton. This present shaft is down 110 feet, perpendicular, and drifts have been run north and south. In 1885, 12 loads of rock, crushed at the Rocky Bar mill, paid \$372.38 per load, a total of \$4,468.56. The last time the mine was worked, which was by a company of tributaries in 1886, the rock paid \$66.25 per load. This is a good showing for any mine and it is confidently expected that, with proper development and management, the Green Mountain can be made one of the best mines in the State.

THE KENTUCK.—Capt. Jno. E. Carter and company are working the Kentucky mine, which is situated a short distance northeast of the Idaho. They have been at work for the past six weeks and the prospects look very encouraging. Last night we were shown some rock taken from the ledge at a depth of about 80 feet, which showed free gold. The ledge from which this rock was taken is from six to ten inches in thickness, and over this there is two feet of cah rock. On top of this again is a ledge of low-grade ore about four feet in thickness. The cah between the two ledges will pay for crushing. This mine was last worked about seven years ago and then showed good prospects.

KEYSTONE MINE.—Grass Valley Telegraph, Feb. 25: For several weeks the old tunnel, worked years ago and running into Alta Hill from the north, has been undergoing a thorough clean-out. Just now the miners have reached the face of the tunnel and they found there the tools used long ago, just how many years we cannot say, for it is beyond the memory of most of us. The tools are at M. Callaghan's place. The drills and hammers, so oddly fashioned, are really a curiosity to the modern miner. The tunnel in the mine is now being neatly repaired and it is in the distance of 700 feet. A track is now being laid and immediately work will be driven toward the great gravel bed that surely exists close by. Messrs. Coughlin, Maiuhart and others are going to spare no pains in unearthing the great treasure hidden in that hill. The indications are that the miners are not far from the famous old channel which made men rich in the early days, and if they should find that ancient river-bed, their courage and energy will be hailed with delight and the promoters could not possibly get too much praise.

THE NATIONAL MINE.—Transcript, Feb. 23: Work is progressing on this property which is situated about three miles south of Graniteville. The mine belongs to the estate of the late D. R. McKillican. Capt. Geo. A. Nihell, manager of the estate, was in town the other evening and had with him some very fine rock taken from the National. The mine is looking better than for a long time.

GRIZZLY RIDGE MINE.—Henry Watson was over from Grizzly Ridge Tuesday and brought with him some handsome specimens taken from the Grizzly Ridge quartz mine. The pieces shown us contained lots of free gold and galena and high-grade sulphurets. The general appearance of the rock was first class. It looks very much like the quartz found in the famous Delhi mine. The Grizzly Ridge mine is situated on the ridge of that name, about three miles northwest of Columbia Hill, and about a mile from the Delhi, with which ledge it runs parallel. The owners are Peter McAusland, George Jones, Henry Watson, Fred Searls, T. B. Gray and C. J. Brand, all of this city, besides others who own more or less stock. The company has been driving a tunnel on the ledge over 130 feet, and last summer when they quit work the shoot appeared to pinch out. But recent developments show that the ledge came in again and better than before. There are now two ledges in the tunnel, one 14 inches wide, the other 6 feet wide. They came together as the tunnel has been extended and are now virtually one ledge. It was some distance beyond the junction, and in the hanging wall, that the specimens shown us were found. The rock averages well and will yield handsomely. Mr. Watson informs us that in the face of the drift there is a strip of gold 1 1/2 inches long and 1 1/2 inches wide, that can be plainly seen. He says he is saving it to show to visitors. The ledge can be traced on the surface for 1800 feet, and experts who have examined it pronounce it the mother lode of the district. Thus far a vertical depth of only 15 or 20 feet has been attained. On the dump are 50 tons of quartz taken from the ledge previous to the present strike. It will yield \$30 per ton in free gold, and the sulphurets are very rich, assaying as high as \$2300. The nearest mill is the Delhi, and the cost of sacking, packing and crushing will not warrant handling the ore in this manner. What is needed is a mill near at hand, and when this is obtained the company feels assured it will have one of the best-paying mining properties in the county. There is a splendid chance to work the mine cheaply by tunnel, while almost unlimited water-power can be procured to drive a mill and other machinery. The company is not financially prepared to erect the necessary mill and will endeavor to sell stock enough to raise the required capital. Within a radius of five miles from the Grizzly Ridge mine there are five quartz mines being worked, employing from 2 to 20 men. The prospects of the district are very flattering. The Live Oak Co. has a ledge 14 feet 6 inches wide, which will mill \$7.50 or \$8 per ton. With such a large ledge the owners would have as

good a thing as they went, if they only had a mill handy to crush their ore.

Mono.

THE BODIE CON.—Bodie Miner, Feb. 24: During the past week east crosscut, 550-foot level, was extended 7 feet. Upraise, 500 level, was extended 9 feet. Upraise from east crosscut, 300-foot level, was extended 8 feet. West crosscut, 200 foot level, Lent shaft, was extended 15 feet.

THE MONO.—During the past week west crosscut from main south drift, 550-foot level, was extended 12 feet. East crosscut from same drift was extended 18 feet. There were employed 4 miners, 1 carmen, and, jointly with Bodie, 1 engineer, 1 blacksmith, 1 watchman, 1 foreman.

CANNON-BALL MILL.—J. H. Kinkead, superintendent of the Occidental mine at Virginia, arrived Tuesday, and has been engaged in getting his cannon-ball mill in perfect working order, preparatory to making a test run on ore from the Summit. Should the run prove satisfactory, the mill will be purchased by Supt. Kelly for the Bulwer Company. This is the first mill of the kind made, and was successfully used at the Occidental. Since then Mr. Kinkead has patented another one, which he considers an improvement over his first invention.

San Diego.

SALES IN JULIAN DISTRICT.—Sentinel, Feb. 23: Four mines in the Julian district have changed ownership this month. As they were all purchased for cash by parties who are able and intend to develop them, it is not a bad beginning for the new year. As the *Sentinel* has repeatedly remarked, "all this camp needs is capital and mining brains."

Shasta.

SHIPPING ORE.—Redding Free Press, Feb. 25: Kingsbury & Hubbard, of Igo, shipped a wagon-load of rich ore to San Francisco last week. Wm. P. Miller, the mining man, has been granted a patent for recovering precious metals. We learn that George Forbes and Sidney Dale discovered an exceedingly rich quartz deposit in Rich gulch, near Churntown, this week. Captain Taylor and Fred H. Deakin, of San Francisco, were here this week. We understand that they have formed a stock company to work a mine owned by them in the Lower Springs district. They expect to put 20 men at work soon running tunnels and sinking shafts. Dan Haskell, since his return from San Jose, has been attending to his mining interests near Iron Mountain. Dan, with others, owns the Little Nellie, an extension of the Little Nellie, and has been quite encouraged by the discovery of some very rich rock in the breast of his 300-foot tunnel. He has a fine, large ledge. There is a fine specimen of ore weighing about 100 pounds at the express office, which came from the Uncle Sam mine on Squaw creek. It was sent down by Mr. James, the superintendent, and was intended for the Shasta county exhibit at the Mechanics' Fair, but came too late. It is an elegant specimen, very rich. It will probably be sent to the World's Fair. J. H. Morton informs us that the prospects are excellent in the Mammoth mine at Old Diggings. In his tunnel, over 200 feet from the surface, he has a five-foot ledge and the rock assays \$60 to the ton. Mr. Morton is developing an excellent property. The last payment for this mine was made last week by Mr. Chayney, the Philadelphia banker who represents the syndicate that made the purchase some time since.

LOWER SPRINGS MINES.—Cor. Shasta Courier, Feb. 25: Some three weeks ago mining men came up from below to investigate into the merits of the Deakin and Taylor mines. Everything looked favorable, as far as ledges were concerned, and they came up again yesterday in order to make still further examination of the whole property. They seemed to be well pleased with the situation of things in general. The amount of ore shipped during the last two years from the Taylor ledge certainly shows the best prospects of any ledge in this district. It is sufficient to warrant capital to take hold of the mine in good shape. The next best ledge upon this property is the Spanish vein, which is a strong, continuous ledge. This lode was worked quite extensively by the Potter Company many years ago. The croppings prospect very well in places. The old workings are all filled up and obstructed, so this vein is in very bad shape to entice any expenditure upon the ledge. Considerable trouble is brooding over on the Middletown side. It appears that a Dutchman is trying to hornswoggle up some of our gold-bearing ledges through an agricultural patent, the same as has been done here in many cases. I supposed all of the red-soil grabbers had gone in their holes and pulled the holes in after them, but such is not the case. The miners ought to arouse themselves to action, fall into rank, and file a protest against such an evil. If the miners would talk less and do that which they ought to, they could certainly wipe out this fraudulent way of obtaining mineral land by claiming it to be agricultural land. A large number of our best quartz ledges here in this district have been captured by patents covering 160-acre tracts. The area of mining ground for prospectors is getting quite limited, and steps should be taken to secure from railroads and other corporations that which is left.

FINE ORE.—Shasta Courier, Feb. 25: Last week the Schroter boys set the water-power pump going and cleaned out the shafts on the Schroter or old Ned Reese mine near the hospital, about a mile north of Shasta, and this week they struck some fine ore. Grant and Arthur Schroter and Lew Stark are working on the mine and taking out ore. They have a cannon-ball water-power mill at the mine, but they expect to ship the rich rock. We understand that Deakin & Taylor have

bonded, or made arrangements to bond, their mines at lower Springs, near Shasta, to San Francisco parties, and that work will be commenced on the property soon on a big scale. The property is a good one and will justify development. A good many Chinese are working in the placer diggings along Clear creek. One company of about 15 are working at Horse-town and taking out considerable dust, but how much no white man "sarveys," for the Chinese are rather uncommunicative on this subject. We hear it rumored that the old Buuker Hill mine, between Shasta and Middle Creek, will change hands in a short time. The mine was lately bonded from the old owners by Wm. Murray and S. Hull of Shasta, and negotiations have been pending for some time for a transfer of the mine to a combination of capitalists. Bunker Hill was one of the bonanzas of Northern California in the '60 period, but litigation kept the mine tied up many years. There is no doubt but that active development would reveal gold deposits as rich, or richer, as any found in early days, and since Murray & Hull bonded the property they have discovered some flattering prospects. If the proposed deal is effected, the new company will put up a mill on Middle Creek and work the mine on an extensive scale. We understand that some Colorado mining men will be here in a short time to examine the property. Joe Woll, of Shasta, has a contract with the Dog Gulch Co. to run a tunnel on one of their locations on Clear creek, about five miles west of Shasta, and is getting some good prospects. The Dog Gulch property consists of some 13 different claims, including the old Strond ledge, and is owned by a Colorado mining man, N. N. Brown, who is at present in Europe, hence little is being done on it at present. We understand that Supt. Cammon is expected out here soon, and that substantial developments will be made on the property in the near future. Alfred Hargrave found a chunk of quartz weighing one pound in the old Drummond mine, on Spring creek, a few days ago, which, when pounded in a mortar, yielded \$54.50 in gold. The final payment on the Mammoth mine at Old Diggings, sold some years ago by Garrecht, Young, Panter, Hop-ping, Bell and others of Shasta and Redding to an Eastern company, was made a few days ago and the purchase of the mine closed. The Mammoth is one of the best mining properties in the county, and the company will make things hum there in a short time. Mc-Timmons & Sonnerhouse have had a force of half a dozen men at work on the Gypsy mine at Lower Springs. The ledge, at a depth of less than 40 feet, is three feet wide and promises to develop into one of the best mines in this vicinity. Work is still being pushed on the hidden Treasure, at Iron Mountain, and a small force is working at the Little Nellie. Frost and his partner Snow, who took out about \$2500 near the old Cannon House a short time ago, are still obtaining good returns from their claim. Frost recently came from Siskiyou, and sold a half-interest in the mine to his present partner for \$30 just before making the big strike.

Sierra.

AT SIERRA CITY.—Mt. Messenger, Feb. 25: Mr. Gray and Mr. T. Burke, two experts from Redding, were here looking at the Phoenix mine and property recently. They took back with them photos of the mine, also samples of the rock to test. The Buttes and Phoenix mills have started to work again. They have been closed owing to the recent storms having blocked the ditches. John Mansfield, while working on the Buttes flume, froze his hands and feet.

YOUNG AMERICA.—A tunnel is being run at the Young America mine, with a view to tap a ledge that was very rich in the upper levels, but which pinched out. Those best posted are confident that the ledge will come in again farther along.

WIDA AWAKE.—About 24 men are employed at the Wida Awake drift mine. This claim is doing well we understand.

Siskiyou.

TUNNEL.—Yreka Journal, Feb. 25: J. M. Lut-trel, who has charge of the Pacific Coast Mining Co.'s claims at Indian creek, owned principally by the well-known steamship firm of Goodall, Perkins & Co., and himself, has run a tunnel about 500 feet in length, to tap one of the three ledges, and expects to reach the ledge in a few more feet. He has considerable trouble with water, requiring the use of canvas roofing to shed the water. The ledge prospects rich at the surface and will no doubt yield handsomely when stoping is commenced in the tunnel. Lee, Lash & Co., of the Greenhorn blue gravel mine, intend forming a reorganization of their company for working their mine on a more extensive scale, now that it is certain of proving a profitable paying property. They have been doing a vast amount of work in opening the claim with but limited means, and need capital to carry on the work successfully. We hope they will succeed in their undertaking, as the thorough opening of the rich gravel bed on Greenhorn will undoubtedly be the means of realizing a great yield of gold, as the blue gravel taken out has all shown very rich prospects.

Trinity.

TAYLOR'S FLAT.—Cor. Trinity Journal, Feb. 25: The Tunnel and Mining Company are at present repairing their ditch and flume, the stormy weather having done quite an amount of damage to it. They have worked off about 24 acres of ground, and there have been taken out about 400 pounds of gold from it. Mr. C. L. Griffith, who has charge of the mine, when the water failed had several prospect drifts run in the ground, and found large prospects in all of them. We are looking for him up at any time to commence work after the ditch is repaired. All the miners are at work, as water is plenty.

We have a boom in embryo here. When it will blossom out I cannot say. Some of the boys went up French creek last fall; they found good prospects in gold that carried quartz, but no quartz that carried gold. There are four distinct belts of rock with the contacts well defined; the main belt that forms the dividing ridge being a hard steel-blue rock, next a serpentine belt, next a soft porphyry, then a slate and last, on the north side, what we miners call granite. Some quartz has been found, but in bunches or pockets only—no regular ledges. They got a good gold prospect, one piece weighing \$3.50. The gold was all coarse and very rough, except the larger pieces, which were somewhat smooth; but it was all what miners would call quartz gold, even this largest piece having some quartz attached to it. The boys have made a fine pack trail up to within four miles of the head of the stream, and next summer they will try to find out whether it will be a boom or a fizzle.

THE TRINITY RIVER MINES.—Cor. Trinity Journal, Feb. 25: Nearly all the mining going on in the vicinity of Cox's Bar is done by Chinamen. At Hall's flat, one mile above Cox's Bar, is the Tom B. Price mine. Mr. Price spent 12 years in running a drift 600 feet long in the upper part of the claim. While running the drift he had to haul timbers for a mile and a half. This claim is now leased by the Ah Get & Ah Tow Company. There were 11 men working, and they were working hard at the lower end of the claim, where they had a giant with a six-inch nozzle. The ditch is a mile and a half long, bringing the water from Sawmill creek to the claim with a pressure of 70 feet. There are two lines of sluices, 12 and 20 boxes long. There are many very heavy boulders, and the Chinamen are compelled to do a great deal of blasting, 25 pounds per day being the average. One of the most intelligent of them told me that the powder for the season's work would cost \$800. The bank is about 40 feet high at this point, and the Chinamen are working at a great disadvantage, owing to the poor dump for the debris. They seem, however, to believe the claim to be rich. According to all reports, it has been rich in the past, and, as they are opening up new ground, it may prove to be as good as ever. The Keeley claim at Manzanita flat, opposite Tinsley's, is leased to a company of Chinamen, of whom there are ten working it by drifting. This is said to have been very rich ground. At Cox's Bar, a mile below Tinsley's, there are a number of Chinamen cleaning bedrock, and perhaps a half a mile below them is the claim belonging to W. A. Pattison; but, as a heavy storm was in progress at the time of my stay there, no work was being done and I did not visit the claim. I propose to do so on my return up the river. A half mile below Pattison's there is a suspension bridge, holding the pipe which supplies the water for the claim at Vance's Bar, now being worked by Geo. W. Tinsley, Geo. E. Harrington and Joseph W. Gore. We saw some of the dirt panned out, and it was very rich. We propose to visit this claim again on our return up the river.

Tuolumne.

ENCOURAGING REPORTS.—Sonora Democrat, Feb. 25: Reports from the mining district of Rawhide are encouraging. About 40 men are employed, and the ore is looking well. Lonis Page is working away on his pocket mine on Brown's Flat. He says the prospects are encouraging, and that good results will be realized. The Jo Hooker mine, situated 2½ miles above Soulsville, is looking encouraging. The vein increases in size as depth is attained. The ore shows free gold. Two hundred pounds of it was shipped to San Francisco this week for assay. W. C. Oakes, the progressive and persevering miner, is going to considerable expense in opening up an old mine on Brown's Flat. The property in former years was known as the Fox & Elliott claim, and is said to have been fabulously rich. The Dutch mine at Quartz Mountain is showing up some high-grade ore. In this locality is the Golden Rule mine, in which a body of rich ore has been struck. Seven men are employed in this mine, merely doing development work. If the recent rich strike is to the extent we have been informed, it is more than likely that proper facilities for working ore will be erected on the property. A rich vein of ore has been developed in a mine owned by Messrs. Ryan, Gloster & Cook, which is situated on Spring gulch, between the New Albany and Buchanan mines. The property is bonded to A. W. Moulton of Oakdale, and that gentleman has had a force of men working for several months, opening up the vein, which is from five to eight feet in thickness and very rich in free gold.

Yuba.

PREPARING TO HYDRAULIC AT SMARTSVILLE. Marysville Appeal, Feb. 25: Several persons who have recently visited at Smartsville informed an Appeal reporter that the Excelsior Water and Mining Company is making preparations to commence hydraulic mining as soon as the Camentti bill becomes a law. The pipes are being laid down and a dam will be soon erected to control the tailings. The old dumps will be cleaned out and a large number of men will be put to work soon. The State Anti-Debris Association will probably have the works inspected as soon as they are complete.

NEVADA.

Ferguson District.

THE LADDER IMPROVING.—Pioche Record, Feb. 25: The ledge cut recently in the Monitor tunnel of the April Fool group of claims, Ferguson district, improves with every foot driven on it. It now averages over eight feet in thickness, and assays from it show it to run \$50 a ton and upward in gold. This in itself becomes at once a wonderful property, leaving the April Fool claim aside entirely. This estimate of assay value is corroborated by non-interested parties who secured samples

from the face of the ledge. On account of the remoteness from any general reduction plant, however, the ore is not to be shipped. The owners are conferring with Denver parties, who offer to furnish reduction works most suitable for the ore if the claim-owners will but ship them a sufficient quantity to Denver for reduction to enable them to determine the best works to supply, and to take their pay for the works in a royalty of so much a ton on ore worked. This the boys think favorable of doing, and a few months hence may witness a reduction plant in active operation at the April Fool mine.

Pioche District.

ARBORENTIFEROUS GALENA.—Pioche Record, Feb. 25: Messrs. Schofield, Spillman and Flynn have struck a fine body of galena ore, assaying from 150 to 184 ounces in silver and 60 per cent lead, in the "Old Timer" tunnel, one of their claims, three miles west of town. The mineral has every appearance of holding out, and if it does it will be one of the finest discoveries made in this county for years past. The Polaris Mining Co. has finished the erection of its steel whim over an 80-foot shaft lying southeast of its present whim shaft on the Poorman mine, and has already sent the new shaft down some 30 feet. It expects to cut the Poorman ledge at about 140 feet from the surface. W. S. Godhe has sold to Jesse Orwin and others, of Beaver, Utah, material for a 10 stamp quartz mill which is to be erected at the gold claims recently discovered some ten miles north of Beaver. The millstuffs disposed of goes from the Dry Valley and the Bristol properties. S. T. Godhe has been expected here for some time with new parties interested in the Pioche Co. property. It is now reported that he will not come before the first of the month and possibly later. He wrote a friend here recently that he hoped his visit would result in some work going on with the property, and that, too, in a short time.

Robinson District.

THE JOANNAH MINE.—White Pine News, Feb. 25: Everybody says the Joanna has been sold and the first payment made. This is probably true, though we are not in a position to speak by the card. In any event, there is no need of our people getting unduly excited over the matter, as it will be some time yet before active work will commence.

MONTANA.

AROUND BUTTE.—Inter-Mountain: There is nothing of importance to chronicle in the mining industry in this district this week. The large silver mills of the district, with the exception of the old Alice mill and the Blue Bird, are dropping their stamps as usual. Speculation is still rife as to the probable date of resumption of the Anaconda and syndicate properties. Everything is in readiness to resume the moment the signal is received, and it is believed that this will not be long delayed. The mines of the Boston & Montana Co. were worked with a reduced force during the week, and the number of unemployed men around the city was considerably augmented in consequence; but during the latter part of the week all the men were placed to work again, and ore for the Great Falls smelter is being produced with its old-time regularity. The Butte & Boston Co.'s works and mines are all in operation. The Silver Bow mill is in operation and is treating ore purchased from leasers, and is also working a quantity of the oxidized ore from shaft No. 2. Silver Bow shafts Nos. 1 and 2 are the chief sources of supply for the company's smelter. At shaft No. 2, which contains a quantity of oxidized ore, work is steadily progressing. While silver was quoted at a fair figure much of this oxidized ore was worked, but since the decline in the price of the white metal, it is only where large quantities of this ore can be easily mined that the work of mining and treating it will pay. On the east Grey Rock, one of the properties of the above company, is located one of the largest engines of the district. This mine is in steady operation. It is said that the Colorado smelter is not producing the same quality or quantity of matte as in former times. Most of the ore for the smelter is obtained from the Gagnon, which, in its early days, was considered a silver mine, but now the property ranks as one of the great copper mines of the district. Occasionally rich bunches of silver ore are encountered in its workings. The other mines of the company are the Philadelphia and Nettie. Operations are not very lively on the two last-named properties at present. Considerable ore is purchased from leasers by the Colorado smelter. The Butte Reduction Works has not employed its customary force of men during the past winter. The concentrator attached to the works has been idle the greater portion of the time. The chief source of supply for these works are the Colusa-Parrot, Original, Travonia and some other small properties. All the ore at the works is now desulphurized in kilns and the old roast-heaps through which pedestrians had to wade in the old days have been entirely removed. The Parrot smelter obtains its supply of ore from the Parrot and Moscow mines and from D. G. Bricker's lease on the Virginians. It is rumored that the Parrot Company expressed dissatisfaction at the recent smoke agitation, and that some of the stockholders had stated that if the company was required to build a stack as suggested by the citizens of Butte, the smelter would be moved elsewhere. The north lead of the Parrot mine becomes more valuable as depth is attained. But few men at present are employed in leasing. The favored locality for this persevering class is along Missoula gulch and the water-sheds running into it. Some of the promising Walkerville properties are the Goldsmith, upon which considerable work is being done, and the Amy & Silversmith, Bonanza, Boston and Pollock. The Mountain View shaft has attained a depth of 1000 feet, and most of the

work of development is confined to the bottom level. This mine has ore enough in sight to last for a number of years. One advantage possessed by the Mountain View is that, being situated so close to the Anaconda properties, the latter properties drain it. The pumps at the Mountain View are only operated about two hours each day. The mine is all at work again on this property.

NEW MEXICO.

A BRIGHT OUTLOOK.—Southwest Sentinel: The mining outlook for this section is considerably brighter now than it was a few months ago. Assurances come from the Mogollons that the season there will be one of great activity. The Colonial Co., operating the Maud S. mine and mill, is now one of the largest producers of bullion in the Territory, and the Confidence Co. will soon have a mammoth mill in operation on ore from the Confidence group of mines. There is a prospect that the Last Chance property will be worked profitably, and work has been commenced on other mines in the camp. Until last year the mines in that camp had been worked at a disadvantage, on account of insufficient facilities for treating the ore in the camp. The distance to railroad transportation is so great that it does not pay to ship any but the highest grade ore to outside points for treatment. The mills of the Last Chance and Colonial Co. were completed last year, and the Confidence Co. will probably have the largest mill in the Territory completed there this year. The outlook at Pinos Altos is very encouraging. The Manhattan Gold M. and M. Co.'s tunnel is nearing completion, and when it is completed the company will commence to take out ore for the mill here. On completion of the tunnel the company will be able to mine ore considerably cheaper than it has been mined by the company heretofore, and it is expected that the mines can be operated as successfully as the Pacific Gold Co.'s mine which is on the same lead and is now producing ore enough to keep two mills in operation. The output of the Mountain Key, Bell and Stephens' mines and other properties in the district is expected to be considerably more than last year, and the new strike made near the Silver Cell is expected to become a good producer. Some good ore is being taken out at Black Hawk, and there is considerable development going on there which may result in opening up large bodies of ore. This district always produces rich ore, and development work never fails to open new bodies of ore in any of the mines. Dimmick, Laizure & Fronger have their shaft down 25 feet on the Grey Eagle mine and the vein is steadily growing wider. They will take out ore enough for a mill-run, when it will be tested. The ore looks well and will probably run high. If the project of getting cheap coal at Hanover is carried out, that camp will be the liveliest in the Territory before the end of the year. There is practically no limit to the ore in the district and the immediate vicinity, and with reduction works there there would be room for thousands of miners and laborers. All the ore produced is of a smelting character, and with cheap coal a larger smelting plant could be kept in operation than there is now in New Mexico. The future of this camp depends entirely upon the fuel question. If coal can be brought from the fields near Gallup and delivered at Hanover at as low a rate as it can be delivered from the mines in the northern part of the Territory to the Socorro smelter, there is no reason why large smelters could not be operated at Hanover, and it is not improbable that iron works and rolling mills will be put into operation. The outlook for lead camps in this county is not so good as it was some months since, on account of the low price of lead; but it is not believed that this materially curtails the production. The repairs on the custom mill at Gold Hill are about completed and the mill will be started up on custom ores in a few days.

OREGON.

THE VIRTUE MINING CO.—Bedrock Democrat: The explorations and developments made since the Virtue Mining Co. came into possession of the Virtue mine, in the operation of which the Virtue Mining, Milling and Development Co. made such a dismal failure, much to the disappointment and loss of many of the business people of this community, are such as to fully warrant the belief that the stockholders in the new company have a bonanza. Since taking charge of the mine, Mr. N. S. Wight, manager, has had a force of miners at work in the upper level above water, awaiting the arrival of a new pump to clear the lower workings of water. In the upper level a good, strong ledge is exposed fully three feet in width and wonderfully rich in gold, samples of which show free gold in large quantities. From this ledge about 125 tons of ore have been taken out and are now in the bins at the mill awaiting reduction, and it is expected that the 10-stamp mill will be started crushing this week. Mr. Wight and Mr. Borman came in from the mine on Sunday evening, bringing with them quite a large quantity of ore which they broke from the face of the ledge before leaving the mine. The ore contains a large quantity of sulphurets, predominating, however, in free gold, an assay of which would probably give a value of \$20,000 to the ton. Yesterday the expected Cornish pump arrived from the East and will be taken at once to the mine and put in place for clearing the lower levels of water. This will be accomplished in 30 days after the pump starts and then an additional force of miners will be engaged in taking out ore from the ledges said to exist and from which there is already about 250 tons of ore in the drifts, mined by the former company, and which was not taken out on account of the breaking of the old pump and subsequent filling up of the mine with water. If properly managed, it now seems that the Virtue Mining Co. has unusually bright prospects, and its success is assured.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING FEB. 21, 1893.

- 492,257.—COOKING APPARATUS—J. S. & C. E. Baker, Newburg, Or.
492,259.—LEMON-SQUEEZER—C. W. Barrett, Lemoore, Cal.
492,265.—CONDUIT ELECTRIC RAILWAY—F. W. Brann, Oakland, Cal.
492,324.—RAILROAD FOR CARTADOES—Chambers & Gruber, Bitter Water, Cal.
491,896.—PINCH BAR—Combs & Frates, Ione, Cal.
492,284.—EXTENSION TABLE—Graff & Harbaugh, Portland, Or.
492,331.—ROPA SHEAVE OR WHEEL—J. W. Kerr, S. F.
492,034.—CAN-SOLDEARING MACHINE—A. W. Livinston, S. F.
492,040.—RECOVERING PARCIONS METALS—W. P. Miller, Redding, Cal.
492,241.—BAIDLA BIT—Sears & Lindsey, Spokane, Wash.
492,056.—PRODUCING DENTAL CEMENT—M. Sichel, S. F.
492,244.—ARMATURE CORES FOR ELECTRIC MOTORS—A. W. Smith, S. F.
492,247.—FOOT-WEARMER—W. E. Ulmer, Honolua, Wash.
492,251.—BRICK KILN—P. L. Youngren, Oakland, Cal.

The following brief list by telegraph, for Feb. 23, will appear more complete on receipt of mail advices:

San Francisco—Clarence W. Bailey, swing joint; Thomas Doyle, rope thread; J. H. Coffran, L. Hill, apparatus for controlling pumps; Adolph Schullenberg, ore-crushing mortar; Charles F. A. Sturis, electric burglar alarm; Edwin H. Thomson, apparatus for reducing bituminous rock. California—Samuel H. Bass, Oakland, window frame and shaft; Daniel E. Donegan, Los Angeles, dumping wagon; John Frey, West Berkeley, separator; E. Vander J. Gillespie, San Jose, roll paper holder and cutter; William C. Gilmer, Stockton, combination tool. Oregon—Otto Van Costram, Portland, waterproof suit. Washington—John McKinnon, Colfax, clothes dryer. Arizona—Michael J. Fitzgerald, Aravaipa, tire-tightener.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LEMON-SQUEEZER.—Chas. W. Barrett, Lemoore, Tulare Co. No. 492,259. Dated Feb. 21, 1893. This is one of that class of lemon-squeezers in which a vertically-moving plunger operates within a cup containing a strainer upon which the lemon rests, said cup being provided with a discharge aperture adapted to convey the juice into an underlying tumbler. The invention consists essentially in an open-front cup provided with a vertically-swinging front plate adapted to open and close the cup, said swinging plate carrying the strainer which is moved into and out of the cup by the swinging of said plate. The object is to provide a simple and easily-handled lemon-squeezer, the peculiar advantage of which is, that by a simple and rapid movement the lemon may be inserted to be squeezed and may be discharged after the plunger has compressed it.

BRICK KILN.—Peter L. Youngren, Oakland. No. 492,251. Dated Feb. 21, 1893. This is one of that class of kilns for burning bricks and other wares in which suitable damper-controlled passages and flues are provided to effect the course of the fire and draft in either direction and its ready reversal. The objects of the invention are to provide for the reversal of the fire and draft in a simple and effective manner and to admit hot air into the kiln chamber in such relation to the burning gases as to promote and complete combustion.

CONDUIT ELECTRIC RAILWAY.—Fred W. Brann, Oakland. No. 492,265. Dated Feb. 21, 1893. The object of this invention is to provide for a more perfect protection and insulation of the conductor which carries the electric current within the underground conduit, a means for producing a thoroughly-insulated connection between the trolley which travels in contact with the conductor and the rheostat and intermediate connection with the motor, with means for preventing the grounding of short-circuiting of the current, and mechanical contrivances whereby a more perfect operation of the apparatus is insured.

HORSE-DETACHING.—George Riley, Vallejo. No. 491,815. Dated Feb. 14, 1893. This invention relates to a novel device for disengaging animals from vehicles which they are handling in order to prevent accident occurring by reason of the animals becoming frightened or running away.

PAOSPACKING.—The hills below the snow-line are alive with prospectors, who, with pick, pan and rockers, are making grub money, and not a few are rocking out big wages. Last week a couple of prospectors made a rich discovery of gold quartz on Canyon gulch, about a mile above the pest-house. They have already taken out several hundred dollars' worth of gold, and the prospect still continues to yield hand-mortal rock. They think they have a bonanza in sight.

Market Reports.

The Markets.

SAN FRANCISCO, March 2, 1893.

Fine Silver Values.

Fine silver was pretty steady last month, both in London and New York. On the 1st of February the price was 38 1/4 for 925 fine in London, and 83 1/4 for 1000 fine in New York. The highest price for the month was reached on the 17th, when the rates were 38 1/2 in the former market and 84 1/4 in the latter. At the close of the month the rates were 38 1/4 and 83 1/4 respectively. The extremes in both markets for the first two months of the year were as follows:

	London—	New York—
	High. Low.	High. Low.
January.....	38 1/4-16d 38 1/4-16d	84c 83 1/4c
February.....	38 1/4-16d 38 1/4-16d	84 1/4c 83 1/4c

In February, 1892, the extremes in London were 41 1/4-16d to 41 1/4-16d, and for the first two months of that year, 43 1/4-16d to 41 1/4-16d.

Coal Receipts at San Francisco.

The receipts of coal at San Francisco by water, exclusive of the product of Mt. Diablo mines, for February, and for the first two months of the year, compare as follows:

	For	Jan. 1 to
	February.	Feb. 28.
Puget Sound, tons.....	24,082	62,279
Oregon.....	2,600	6,400
Australia.....	400	2,500
British Columbia.....	1,184	15,589
English.....	32,861	80,398
Scotch.....	8,905	17,853
Welsh.....	5,663	5,663
Wales.....	2,142	9,415
Total.....	84,837	200,197
In 1892.....	107,840	245,997

The receipts from Australia and Europe continue light. There were only six cargoes from Australia in the past two months of the year, and about the same number from all ports in Europe.

Coinage of the San Francisco Mint.

The local mint turned out \$2,640,000 in double eagles last month, against \$2,460,000 for the same month last year, of which \$2,200,000 was in double eagles and the remainder in silver coins.

For the first eight months of the fiscal year the coinage compares as follows:

	1891.	1892.
Double eagles.....	\$16,182,500	\$15,500,000
Half eagles.....	412,500	412,500
Standard dollars.....	470,000	700,000
Half dollars.....	160,000	198,720
Quarter dollars.....	604,020	119,000
Dimes.....	326,000	22,901
Totals.....	\$17,742,520	\$16,953,121

Eastern Silver Markets.

NEW YORK, March 2.—Following are the closing prices for the week:

	Silver	Silver
